## A

	Page		Page
Acieral aluminum steel	512	Bennett, Charles	Mill-tests <i>v.</i> hand-sampling... 529✓
Active nitrogen	870	Bethlehem Steel Co., largest ingot mold	543
Advance in electric steel production	321	Bibles, war demand	Editorial... 297
Agricultural land, minerals from	780	Bille, G. C.	Water and mines in Paradise... 851
Alaska, chrome deposits	653	Bi-metallism, international system	935
Engineering Commission	926	Bituminous coal, recovery of pyrite from	385
Gold mines	777	Blakemore, Leonard G.	Prospecting conditions in California... 783
Government railroad	Theodore Pilger... 925	Blast-furnace record	86
Lode-tin in	206	Blasting caps	133
Placer mining	729	Misfires	44
Allen, A. W.	Upflow clarification of solution... 436	Missed holes in a wet shaft	783
Allen, Milton A.	Supply of gasoline... 511	Physiological effect of carbon monoxide	463
Ditto	Trinitro-toluene for mines... 688	Troubles	828
Alloys, British standard	684	Block, James A.	Flotation physics... 675
Acid-resisting	282	Block-stopping and timbering in deep placer-mining	E. E. Fleming... 378✓
Aluminum alloy, acieral	512	Blue-sky law	Editorial... 149
Cables	729	Bolivia, Avicaya mill	343
In cyanide solutions	358	Corocoro copper mines	461
Sulphate	726	Tin-silver district	57
War prices	Editorial... 73	Borax	684
American Brass Co.	308	Boron	243
American Institute of Mining Engineers, St. Louis meeting	Editorial... 525	Bourquin, Judge, decision in Minerals Separation	Editorial... 297
American peace	Editorial... 560	Opinion in Butte & Superior case	464
American Smelting <i>v.</i> Bunker Hill	Editorial... 335, 847	Bradley, F. W.	Editorial... 847
Abstract of reply-affidavits	865	Ditto	Affidavit, American Smelting <i>v.</i> Bunker Hill... 829
Affidavit by F. W. Bradley	829	Bradstreet's index-number	340
Affidavit by E. L. Newhouse	797	Brass	581
Analyses, screen	344	Brazil enters the War	Editorial... 632
Another Mexican crisis	Editorial... 414	St. John del Rey	Editorial... 37
Anticlines, petroleum in	243	Brick from coal ash	536
Antimony	Editorial... 185	Brinsmade, Robert E.	Butte re-visited... 79
In China	904	Britannia Mining & Smelting Co.	Editorial... 411
In zinc	473	British export prohibitions	21
Argall, Philip	Mill-tests <i>v.</i> hand-sampling... 673✓	Standard alloys	684
Argentina, oilfields in Patagonia	91	Broderick & Bascom Rope Co.	Editorial... 813
Arizona, leaching copper ore at Bisbee	749	Brooks, L. W.	Graphite... 391
Miami	T. A. Rickard... 157, 417, 457, 565, 679, 784	Brown, J. Coggin	Solubility of tungsten minerals... 303
Producing mines	468	Bunker Hill & Sullivan	802
Artillery	233	Litigation with A. S. & R. Co.	797, 829, 865
Assaying, cupel-absorption with low-copper	124	Ditto	Editorial... 335, 779
Government surveys	134	Smelter	275
Influence of base metals	124	Burch, Albert	Extra-lateral right... 303
Assessment work, exemption	Editorial... 600, 631	Burma, Bawdwin mine	221
Work, exemption for Army and Navy	Editorial... 73	Tungsten	729
Work, form for exemption	Editorial... 777	Butte labor troubles	305
Work on mining claims	468	Re-visited	Robert E. Brinsmade... 79
Ditto	Editorial... 559	Butte & Superior case, flotation	130
Assistance, financial to families of soldiers and sailors	385	Brief for defendant	168, 207
Austin, L. S.	Recovery of converter-fume at Tooele, Utah... 611	Opinion of Judge Bourquin	464
Australian transcontinental railway	Editorial... 669	Decision	Editorial... 451, 487
Zinc	95	Suit	Editorial... 185, 450
Austria, declaration of war	Editorial... 848		
Austrian Melchizedek	Editorial... 527		
Avicaya mill	M. G. F. Söhnlein... 343		

## B

Bains, Jr., Thos. M.	Physics of flotation... 921
Balaklala precipitating-plant	237
Barite	901
Barkdoll, I. H.	Electric blasting-caps and delay-electric igniters... 133
Barytes, price	718
Production	354
Uses of	91
Bauxite, fused, for furnaces	651
In 1916	864
Becker, Clyde M.	Secondary zinc deposits... 530
Behavior of aluminum in cyanide solutions	358
Bemis Bros. Bag Co.	Editorial... 813

## C

Calcareous marl	675
Calcination of magnesite	653
California blue-sky law	Editorial... 149
Committee on petroleum	171
Compensation law	902
Field artillery	W. G. Devereux... 116
Hidden Treasure mine	Editorial... 185
Metal industry	638
Milling methods	318
Mineral resources for War	Editorial... 373
Mines in 1917	320
Paradise, water and mines in	456, 636, 851
Prospecting conditions in	782
Searles Lake potash	902
Sponge iron in	901
Steel	Editorial... 112
Tungsten	95

	Page
Foods, metals, and labor.....	Editorial..... 672
Pledges .....	Editorial..... 411
Forest Reserve.....	H. F. Melville..... 5
Ditto.....	C. E. Rachford..... 6
Formation of zinc ferrate.....	195
E. H. Hamilton, G. Murray, and D. McIntosh.....	932
Foundations for small gas-engines.....	H. D. Staley..... 711
Freight-rates on drill-steel.....	611
Fume, converter, recovery of.....	651
Fused bauxite for furnaces.....	

## G

Gale, Hoyt S....	Origin of nitrates in cliffs and ledges....	676
Gallium in zinc-blende.....		864
Garlichs, Herman.....	Metallurgy of lead in lower Mississippi valley.....	315
Gas engines, foundations for.....		932
Fires at wells.....		172
Gases, flammability of.....		456
Gasoline from natural gas.....		340
Supply of.....		511
Geologic eccentricities.....	Editorial.....	375
Geology of San Sebastian mine, Salvador.....	C. Erb Wuensch.....	345
Of Telkwa district, B. C.....		54
German cyanide.....		431
Propaganda.....	Editorial.....	487
Giant, see mines.....		
Gilmour, R. E....	Flotation tests with hardwood oils.....	763
Glass, Earl.....	Stadia-reduction chart.....	279
Globules in zinc.....		473
Gold, basis for currency.....	Editorial.....	920
Bullion assaying.....		124
Dredging, recovery of platinum in.....		825
Flotation.....		199, 265
In Montana, first discovery.....		898
International monetary system.....		935
Milling.....		318
Mines, recruiting labor from.....		747
Mining companies excess-profits tax.....		934
Mining, threat to.....	Editorial.....	849
Ditto.....	F. L. Sizer.....	924
Mining, Transvaal.....	Editorial.....	743
Need of large reserves.....	Editorial.....	778
Need of reserves.....		783
Output of Colorado.....		654
Precipitation from copper cyanide solution.....		355
Production in China.....	Editorial.....	444
Reserve, need for.....	L. S. Ropes.....	929
Reserve of United States.....		730
Goodner, Ivan E....	Water and mines in Paradise.....	456
Government copper regulation.....	Editorial.....	1
Lead purchase.....	Clinton H. Crane.....	24
Railroad of Alaska.....	Theodore Pilger.....	925
Grant, Lester S....	A criticism.....	675
Ditto.....	Do we need gold.....	783
Graphite.....	L. W. Brooks.....	391
Prices of.....		468
Grinding ore for flotation.....	Editorial.....	560
Guggenheim, Daniel.....	Editorial.....	298
Guild, F. N.....	Editorial.....	848
Ditto.....	Microscopic features in silver-deposition.....	857
Gypsum prices.....	Editorial.....	559

## H

Hall, Edgar.....	Magnetite and copper.....	492
Hall, R. G....	Factors in the production of electrolytic zinc.....	685
Hamilton, E. C....	Formation of zinc ferrate.....	195
Hand-sampling v. mill-tests.....		529
Ditto.....	Morton Webber.....	125
Hardwoods, fuel-value.....		730
Hardy, Charles.....	Tungsten.....	712
Harrington, J. F....	Missed holes in a wet shaft.....	783
Ditto.....	Plea for labor.....	712
Hastings, John B....	Sampling large low-grade orebodies.....	379
Heap-leaching of copper-sulphide ore.....		
	Courtenay De Kalb.....	749
Heavy blow to mining companies.....		396
Hersam, Ernest A....	Outlook for iron and steel on the Pacific Coast.....	117

Homestake mine production.....		869
Hess, Frank L....	Quality of tungsten ores.....	473
Hill, James M....	Prospecting for platinum.....	474
Hoist, electric.....		356
Holland, L. F. S....	Editorial.....	847
Hollis, Ira N....	Editorial.....	631
Holman, S. A....	Copper-precipitating plant at Balaklala mine.....	237
Holt Manufacturing Co.....	Editorial.....	813
Hookworm.....		684
Hoover, T. J....	Editorial.....	149
And sulphuric acid.....	Editorial.....	528
Help for.....	Editorial.....	222
Howard, L. O....	Mining in Utah.....	189, 397
Ditto.....	What is a metalliferous mineral.....	55
Hubbard, J. D....	Water and mines in Paradise.....	636
Hydro-metallurgy of copper sulphides.....	A. E. Drucker.....	713
Of lead-silver at the Bunker Hill smelter.....		
	Clarence L. Larsen.....	275
v. smelting.....	A. E. Drucker.....	44

## I

Idaho, hydro-metallurgy of lead-silver at Bunker Hill....		275
Mineral output.....		350
Phosphate lands in.....		314
Igawa, Takeo.....	A method of mining.....	852
Ikeda, Kenzo.....	Japanese copper production.....	618
Immigration 1916-17.....	Editorial.....	449
Increased wages and decreased efficiency in the Clifton-Morenci district.....	Walter Douglas.....	339
Index-number of Bradstreet's.....		340
Industrial romance.....		308
Ingalls, W. R....	Zinc-burning.....	432
Ingersoll-Rand Co.....	Editorial.....	813
Inspiration mine.....	Editorial.....	450
Iron, magnetic ores.....		7
Ore, lake output.....	Editorial.....	259
Pacific Coast.....		117
Price fixing.....	Editorial.....	449
Rusting of.....		828
Sponge in California.....		901
Italy, reverses on the Isonzo.....	Editorial.....	919
I. W. W. and Butte.....	Editorial.....	299
Sabotage.....		273

## J

Janin, Charles.....	Russian crisis.....	163
Japan, exports.....		678
Intentions of.....	Editorial.....	186
Mineral output.....		432
Japanese copper production.....	Kenzo Ikeda.....	618
Jennings, Sidney J....	Editorial.....	847
Jerusalem delivered.....	Editorial.....	847
Johannesburg, new organization.....	Editorial.....	670
Journalism and diplomacy.....	Editorial.....	259
Judd, E. K....	Editorial.....	670

## K

Kahn, Julius.....	Editorial.....	778
Kalgoorlie, Western Australia.....		724
Kansas, Kompelter region.....	Editorial.....	672
Karri-Davies, Walter.....	Editorial.....	847
Ditto.....	New Canadian mining district.....	534
Kemp, J. F....	Editorial.....	221
Kies, W. S....	Chemical exposition.....	533
Kiliani, R. B....	Simple methods of finding density and weight of solids in mill-pulp.....	390
King of Arizona Company.....		747
Ditto.....	Epes Randolph.....	674
Kitts, J. A....	Proportions for cement mortars and concretes.....	719
Knox, Newton B....	Solubility of tungsten.....	818
Kompelter region.....	Editorial.....	672

## L

Labor agitators, Mr. Roosevelt and others.....		
	T. A. Rickard.....	239
And I. W. W.....	Editorial.....	706

	Page
Labor, I. W. W. and Butte.....	Editorial..... 299
I. W. W. sabotage.....	273
Mexican in Arizona.....	Editorial..... 555
v. mine production.....	489
Plea for.....	712, 817
Ditto.....	Editorial..... 815
Recruiting.....	Editorial..... 745
Recruiting from gold mines.....	747
Troubles at Butte.....	An Occasional Correspondent... 305
Wages and efficiency.....	339
Lang, Herbert.....	Sponge Iron..... 901
Largest ingot mold ever made.....	543
Larson, Clarence L.....	Hydro-metallurgy of lead-silver at the Bunker Hill smelter..... 275
Lass, W. P.....	Chrome deposits of Alaska..... 653
Lassen, Mt., California.....	206
Lauder flotation machine.....	B. M. Snyder..... 201
Law, oil legislation needed.....	Editorial..... 151
Leaching and purification of zinc sulphate.....	

	K. B. Thomas.....	724
Copper ore .....		749
Lead, antimonial .....		468
Flotation in the Joplin district .....		575
Government purchase .....		24
Hydro-metallurgy of .....	Editorial.....	267
Metallurgy in Missouri .....		315
Missouri .....		93
Silver, hydro-metallurgy of .....		275
Leadville manganese resources .....		758
Ledoux, A. R. ....	Editorial.....	670
Liberty Bell mercury-trap .....	Albert G. Wolf.....	206
Liberty bonds .....	Editorial.....	185, 595
Loan .....	Editorial.....	525, 595
Licenses for use of explosives .....		870
Life of cast-iron pipe .....		764
Lincoln, Francis Church.....	Corocoro copper mines .....	461
Ditto.....	Oruro tin-silver district, Bolivia .....	57
Lindsay, Robert .....	Precipitating gold from copper cyanide solution .....	355
Lithium .....		356
Litigation, flotation .....	Editorial.....	223
Loring, W. J. ....	Editorial.....	633
Ditto.....	An interview by T. A. Rickard .....	639
Lost mines .....		678
Louisiana petroleum .....		86
Lucas, Anthony F. ....	Editorial.....	885
And the Beaumont gusher .....		887
An interview by T. A. Rickard .....		887
Lynching at Butte .....	Editorial.....	187

## M

Magmatic ore segregation.....	J. A. Dresser....	7
Magnallium .....		654
Ditto .....	Editorial .....	374, 814
Magnesite, calcination of .....		653
Consumption in steel-making .....		380
Occurrence .....		460
On the Pacific Coast .....		203
Precipitation .....		432
Uses .....	Editorial .....	335
Magnesium in magnallium .....	Editorial .....	814
Price .....		827
Magnetic separation .....		508
Magnetite and copper .....	Edgar Hall .....	492
Ditto .....	H. W. Turner .....	818
Making a career .....	Editorial .....	633
Of an American .....	Editorial .....	885
Manganese .....	Editorial .....	705
At Philipsburg, Montana .....		116
Crisis in trade .....		264
Deposits of Philipsburg, Montana .....		725
Ferro .....		304
Ferro, American requirements .....	Editorial .....	1
Ferro, prices .....		762
In furnace slags .....		617
Investigations .....		726
More needed .....	Editorial .....	263
Output .....		578
Panama .....		233
Requirements .....	Editorial .....	263
Resources at Leadville .....		758
Manitoba, new mining district .....		534
Marl, calcareous .....		675
Mason, F. H. ....	The nitrate fizzle .....	226

	Page
Mason Valley Mines Co.....	Editorial..... 777
Mathewson, E. P.....	Flotation process..... 472
McIntosh, D.....	Formation of zinc ferrate..... 195
McLaren, Alex.....	Modern milling methods applied to California gold ores..... 318
Mechanical ventilation for metal mines.....	George Rice..... 579
Mekler, L. A.....	Russia in war time..... 710
Mellon Institute.....	Editorial..... 297
Mercury-trap.....	206
Metal, base, foreign trade.....	Editorial..... 411
Government committees.....	Editorial..... 669
Non-ferrous exports.....	543
Production by States.....	456
Scrap shipments.....	Editorial..... 297
Metalliferous mineral.....	55
Mineral, definition.....	221
Metallurgy, hydro.....	A. E. Drucker..... 44
Of lead in lower Mississippi valley.....	Herman Garlich..... 315
Method of construction of concrete and timber flume for Cove power project.....	356
Of filing drawings.....	Albert G. Wolf..... 426
Of mining.....	Takeo Ikawa..... 852
Ditto.....	George J. Young..... 637
Mexican labor in Arizona.....	Editorial..... 559
Menace again.....	Editorial..... 75
Mining difficulties.....	Editorial..... 150
Postal facilities.....	Editorial..... 37
Mexicans, food for.....	748
Mexico, a refugee from.....	Editorial..... 526
Another crisis.....	Editorial..... 414
Bullion restrictions.....	Editorial..... 595
Cash needed.....	221
Conditions in.....	Editorial..... 847
Cyanidation v. flotation at Pachuca.....	94
Joint convention.....	Editorial..... 373
Loans for food.....	Editorial..... 669
Lower California oil.....	Editorial..... 260
Opportunity for reconstruction.....	Editorial..... 745
Protection to American-owned mines.....	Editorial..... 38
Recollections of.....	By a refugee..... 531
Restriction of gold and silver exportation.....	Editorial..... 847
Santa Eulalia.....	869
Villa still active.....	Editorial..... 559
Miami, Arizona, the discovery—I.....	T. A. Rickard..... 157
Mining of the ore—II.....	T. A. Rickard..... 417
Mining of the ore—III.....	T. A. Rickard..... 457
Milling of the ore—IV.....	T. A. Rickard..... 565
Milling of the ore—V.....	T. A. Rickard..... 679
Smelting of the ore—VI.....	T. A. Rickard..... 784
Miami Copper Co.....	Editorial..... 297
Michigan copper-tailing.....	757
Microscopic features in silver-deposition.....	F. N. Guild..... 857
Mill-pulp, determination of density.....	390
Mill-tests v. hand-sampling.....	Philip Argall..... 673
Ditto.....	Charles Bennett..... 529
Ditto.....	Stanly A. Easton..... 636
Ditto.....	L. A. Parsons..... 731
Ditto.....	R. E. Raymond..... 635
Ditto.....	F. F. Sharpless..... 638
Ditto.....	H. R. Sleeman..... 563
Ditto.....	E. P. Spaulding..... 301
Ditto.....	Morton Webber..... 125, 453
Millman, John T.....	Screen analyses..... 344
Mine, California.....	320
Found by thieves.....	86
Giant, Rhodesia.....	Editorial..... 1
Lost.....	678
Rescue apparatus, use and testing.....	234
Russian, American control.....	Editorial..... 37
Sampling.....	301
Taxation.....	Editorial..... 884
Mine & Smelter Supply Co.....	Editorial..... 813
Mineral, definition of metalliferous.....	221
For war.....	Editorial..... 918
Metalliferous.....	55, 225
Output of Idaho.....	350
Output of Japan.....	432
Production, Montana.....	232
Minerals Separation.....	Editorial..... 259, 373, 412, 778
And Canadian patent law.....	Editorial..... 396
Blow to mining companies.....	Editorial..... 743
Criticisms at Cobalt.....	Editorial..... 670
Miners advance.....	728
Regiment of.....	

	Page
Political economy .....	492

## "KEWANEE" Flange Unions

- ¶ Brass-to-iron ground ball joint insures a non-leaking connection even when the pipe is out of alignment.
- ¶ Flange is loose on the collar—the bolts match the holes in any position of the flange.
- ¶ "KEWANEE" Flange Unions are tested with extreme compressed-air pressure under water and if not absolutely tight are rejected.
- ¶ The brass ground-in seat is not loosely inserted, but is made practically integral with the malleable part of the Union.

Fig. J-335—Sectional View

Note Brass Seat Screwed In

¶ THE WHOLE "KEWANEE" FAMILY booklet tells all about "KEWANEE" Flange Unions, "KEWANEE" ring type Unions and "KEWANEE" specialties. A copy will be sent free to anyone whose letterhead or position would indicate a legitimate use.

# THE OLIVER

has never been replaced by another make of filter, but other filters are continually being replaced by *Olivers*.

The OLIVER is made in sizes to meet any condition involving the separation of liquid from solid.

The OLIVER can lower the percentage of moisture in your concentrate and at a lower cost than by any other method or apparatus.

The OLIVER can eliminate your soluble losses and reduce your cyanide and zinc consumption, whether or not you use countercurrent decantation.

The OLIVER is the standard filter—universally known and universally used.

Write us today and send 5 gallons of pulp—we can solve your filtering problem.

**OLIVER CONTINUOUS  
FILTER COMPANY**

501 Market St.

San Francisco

*No Royalties to Pay*

# Why Trust to Luck to Save Gold

But take such pains to save the concentrates?

In tests made by the General Engineering Co. the Senn Batea Amalgamator, Jr., amalgamated 97% of the gold from Neill Jig concentrates. Of this gold 55% passed 100 mesh.

## Can You "Pan" Free Gold in Your Plate Tailings?

The Victor recovered 14 ounces of amalgam on the Senn Batea Amalgamator from stationary plate tailings to 20 ounces on the plates.

An increase of 25 cents per ton means an increase of \$375.00 per month for each Senn Batea.

## Why Not "Pan" the Gold into the Amalgam?

In tests by Chas. Butters Co. on a silicified shale carrying free gold, the best of four laboratory bottle amalgamation tests gave 58.5% recovery. Two mill runs on the Senn Pan-Motion Batea Amalgamator gave 78% and 82.5% respectively.

We are furnishing 4 Bateas for the first unit of the mill to handle this ore.

## Why Not Grind Fine and Save All the Free Gold?

63% of the gold in the latter tests passed through 150 mesh, while 91% of it passed 40 mesh.

## Senn Pan-Motion Batea Amalgamators

are made in two sizes—a 50-ton machine for general mill installations, and a 20 to 25-ton Batea (shown above) for test plants, small mills, clean-up plants, cleaning placer concentrates, etc. They are carefully and strongly built for continuous operation with a minimum of attention.

# DUPLEX RESERVE POWER ASSURES DEPENDABILITY IN EXTREME EMERGENCIES

**T**HE tremendous reserve power of the Duplex—the original 4-Wheel Drive  $3\frac{1}{2}$ -Ton Truck—is applied four times more effectively than is possible with any other type of motor truck.

That is why the Duplex is known throughout the country—in industrial centres, logging camps, gravel pits, mining districts, deserts and oil fields—as a super-strength motor truck that hauls capacity loads anywhere.

One source of Duplex dependability under most adverse road conditions is found in the Duplex-Adler self-locking differential, which automatically throws the power to the wheel or wheels having traction.

Another source of Duplex effectiveness of reserve power lies in the range of gear reduction made possible with the Duplex Chain Case—an exclusive Duplex truck feature.

The Duplex Chain Case reduction gives the Duplex a draw-bar pull four times greater than that of any rear-wheel drive truck, and

makes it practically impossible to stall the Duplex even when trailers are being pulled through hub-deep mud and up embankments.

The Duplex Chain Case, by means of a silent chain belt, transmits the power from the main propeller shaft to the shafts driving the front and rear axles. A reserve chain provides an additional two to one gear reduction whenever needed. This chain case reduction practically doubles the power applied to the four wheels. It provides a tremendous leverage of 64 crank-shaft turns to every revolution of each of the four wheels, and makes it possible for the Duplex to haul three and one-half ton loads under up-grade conditions that any rear-wheel truck would find difficult to negotiate when unloaded.

Our 1917 catalog explains in detail the many exclusive mechanical features of the Duplex, while our engineers will give you facts and figures for your particular business. If you would reduce your haulage costs to the absolute minimum, let us send you complete information about the Duplex—the truck that hauls capacity loads anywhere.

*The Duplex  $3\frac{1}{2}$ -Ton Truck, shown above, hauled this large oil tank over country roads a distance of nearly 30 miles. The tank, which is 7 feet in diameter and 28½ feet long, weighs 8½ tons. The Duplex hauled its burden through sand and mud and up steep hills, and clearly demonstrated that it is equal to any hauling emergency.*

# For Stamps

Stamp-milling is the supreme test of stamina in a screen. Five stamps in a single mortar, weighing 1000 pounds and more, dropping from a height of 6 inches at the rate of 100 times per minute, drive with great force particles of rock against the screens. Imagine this constant battering against the screens—the wear and tear and consequent short life. It is not surprising that punched metal was considered the only practicable thing until the advent of

## PERFECT

### Double - Crimped Woven - Wire Cloth

The double-crimping process not only produces a structure exceptionally strong and stiff, but also gives a large percentage of effect-

ive screening area, a point of great importance when the desirability of a quick discharge is considered.

# MATTESON

**M**ATTESON CARS were introduced in 1908. Since then they have replaced practically all other makes in Pacific Coast and adjacent territory. They are 'investment' cars, the cars of exclusive design and workmanship.

These are the  
that distinguish  
from ALL

COMPOUND HINGE

Through this device, the body of the car may be tipped to an angle of 30 degrees from a centre comfortably back of the centre of gravity when the loaded body is at rest. The car may then be dumped with ease from any position, swiveling being possible without release of the door latch.

STANDARD TRUCK

This is made of a one-piece steel channel frame, accurately formed. The Hendy dust-proof axle-housings are bolted on with U bolts. The live axles float and are readily replaceable.

TURNTABLE

This is not like ordinary swivels. It revolves on roller bearings in a dust-proof housing, the upper and lower plates being made of steel. The minimum exertion thus required to swivel the loaded car is obvious.

*There is a HENDY-MADE mine-car  
to suit your requirements*

# MINE CARS

**H**ENDY-MADE means something. It means the combination of the latest manufacturing methods, modern, up-to-date shop equipment, superiority in design, and the best available material for the purpose used.

## exclusive features HENDY-MADE cars OTHERS

The axle consists of a dust-proof housing which is bolted to the frame with 4 bolts. Inside is the steel 'live' axle in two pieces, so that short-radius curves may be negotiated with ease. Both wheels and axles are free to revolve, yet neither can come off unless desired.

DUST-PROOF AXLE

This is the last word in car-axles. As shown, the working parts are entirely enclosed, no dust or grit can get in, and no lubricant can get out. Its use makes a marvelously easy running car, and is practically trouble proof.

OIL-TITE AXLE

These bearings can be applied to cars when desired, and we recommend them without reserve. By their use the draw-bar pull for any load is reduced about 25 per cent; they last for an indefinite period, and require no care beyond lubrication.

HYATT BEARINGS

*Send for catalogues, prices, and  
full information*

## TUNNELING COSTS REDUCED 40%

# ***FLEXOID TUBING***

Trade Mark Registered

Solves one of the biggest problems in tunnel driving—maximum results are now possible.

No more expensive time losses. Men can return to the face immediately after blasting. Smoke and fumes removed in less than three minutes. Air conditions equal to those above ground—results more and better work—no bonuses necessary. Also used in shafts, raises and winzes.

Flexoid Tubing is low in cost and easy to handle. One man can carry and install one or two hundred foot sections in three minutes. Suspended from timbering or laid along floor.

Leading mine operators and superintendents proclaim it the greatest improvement in tunnel driving and mining equipment in years.

**60 Days FREE Trial.** To any responsible mining concern we will furnish enough Flexoid Tubing to give it a thorough trial for 60 days, with the understanding that it may be returned and no charge will be made if it is not entirely satisfactory.

*Ask for further particulars. You will be under no obligations whatever.*

HEADQUARTERS FOR MINE-MILL AND SMELTER EQUIPMENT

## Two Concentrators in One—

Where floor-space is limited or where conditions seem to warrant doubling the capacity without increasing the number of tables, it is easy to meet conditions by simply installing the *new No. 9 DOUBLE DECK*—

### WILFLEY TABLE

**FOR  
WET  
CONCENTRATION**

**A.....  
MASSCO  
PRODUCT**

The actual result obtained from such installation is *two* efficient concentrating tables in the space formerly occupied by one.

And when we have told you that this new No. 9 Wilfley is, in reality, two *number six* Wilfleys—that it actually doubles the well-known advantages of this justly famous table—you will realize the importance of this new development. The No. 9 is rapidly finding

its way, in large quantities, into the largest and most important concentrating plants.

The same superior principles, great care, excellent workmanship and materials that have made the Wilfley Table famous are embodied in the new No. 9 Double Decker.

Of large capacity, depending upon the character of the ore, it gives the service that mining men have learned to expect from all MASSCO products.

Bulletin 30 explains in detail. "Successful Purchasing" is the title of another booklet which means all that its name implies. Both booklets will be sent, without obligation, upon request.

## ECCLESTON MACHINERY COMPANY

162 SOUTH ANDERSON ST., LOS ANGELES, CALIFORNIA

# THE FLOTATION PROCESS

All patent and other rights to this process  
in North America are now controlled by

## MINERALS SEPARATION NORTH AMERICAN CORPORATION

On December 11, 1916, the SUPREME COURT OF THE UNITED STATES adjudged our basic patent for **air-froth flotation** to be valid, holding that this patent covers any process of froth flotation wherein the **results obtained** are secured by the use of a fraction of one percent., on the ore, of an oily frothing agent in an ore-pulp, with agitation. Three of the thirteen claims which specified the use of "**a small quantity of oil**" and which the Court held to be invalid have since, by proper disclaimer, been brought within the scope of the Supreme Court's decision and, at a recent trial in the United States District Court at Butte, Montana, Judge Bourquin admitted these claims as amended.

On May 24, 1917, the UNITED STATES CIRCUIT COURT OF APPEALS at Philadelphia, in the case of Minerals Separation, Ltd., against Miami Copper Company, unanimously sustained the validity and broadly construed a **second basic patent**, owned by us, for the use of all "**Soluble Frothing Agents**." In the same opinion, the Court also validated a third patent for the use of cresols and phenols in the cold and without acid. The defendants, Miami Copper Company endeavored to avoid infringement of these patents by using Callow pneumatic cells, but the Court held that the operations of the defendant company infringed all three patents.

Prospective users of our flotation processes are earnestly requested not to be misled by the mistaken views disseminated by interested parties that any of these BASIC PROCESS PATENTS can be evaded by a mere variation of apparatus for agitating and aerating the pulp, or by the simple addition of oils or other materials in excess of a fraction of one percent. on the weight of the ore treated.

### NOTICE

Notice is hereby given that we will enforce our patents and stop all infringements, but are prepared to grant licenses for the right to use all or any of our processes to those who wish to use them.

To those who infringe or have infringed our patents, notice is given that **A SETTLEMENT FOR SUCH INFRINGEMENT MUST PRECEDE THE GRANTING OF LICENSES FOR THE FUTURE USE OF SAME.**

Notice is further given that no one is authorized to introduce our processes or apparatus into the United States, Canada, or Mexico.

*All applications should be made direct to*

# Single Friction Drum Gasoline Hoist

Exceptional utility is presented in these light, compact, self-contained hoists for mine service.

The drums are of the best quality of cast iron and fitted with renewable bronze bushings; they are controlled by the well known Cone Friction type of Clutch and Steel Band Brake, both lined with hard wood blocks.

The gears are accurately cut from the solid on automatic machines, thus insuring smooth, quiet running and long life. Gear Guards (not illustrated) are furnished.

The Motors are vertical, double cylinder, 4 cycle, giving a steady stream of power. These engines are throttle governed. They are fully enclosed, all moving parts running in a bath of oil. Glass oil-gauge is fitted on side.

Shebler carburetor, jump spark ignition, also high tension, gear driven magneto furnished.

Water Pump is direct driven and non-chokable. A double screen cooling tank is furnished.

Two Sizes 8 H.P. and 15 H.P.

*Nordberg Motor-Driven Hoist with General Electric Motor Generator Set and direct current motor for Elm Orlu Mining Co., Butte, Mont. Load 52,000 lb., depth 3500 ft.*

## Typical Large Electric Hoist— Built by NORDBERG

This hoist is of the large double drum, first motion type, driven by a direct current motor, operated by Ward-Leonard control in conjunction with a fly-wheel motor generator set.

**The clutches** are of the celebrated Nordberg balanced axial plate type, operated by the hydraulic engine shown clearly in the large photograph. These clutches have great power and once used by mining men, are always demanded.

**The brakes** are of the Nordberg gravity operated, post brake design with levers and suspensions to give parallel motion and prevent binding. Brakes are applied or relieved evenly and gradually. With the oil operated hydraulic engine behind

and to the right of the clutch engine, the degree of braking can be regulated with greater delicacy than by hand brakes.

A feature of this installation is the arrangement of rods from operator's platform to brake and clutch engines, in trenches covered by floor plates. This makes the installation exceptionally neat of appearance.

If you are not fully posted on these and other features of Nordberg Hoists, ask for Bulletins 23 and 24.

## HERE IS SOMETHING NEW— The LITTLE GIANT CARBIDE LAMP

**Justrite**  
TRADE MARK  
**CARBIDE  
Mine Lamp**

A LAMP FOR EVERY  
MINING PURPOSE

"When a better carbide lamp is  
made it will be a JUSTRITE"

A true JUSTRITE product in every sense of the word—It is called the "LITTLE GIANT" because it is the lamp of LITTLE weight and trouble, and a GIANT for economy and efficiency.

It weighs only 30 ounces—has the famous JUSTRITE Spiral Water Feed with the Removable Spiral Valve Stem—Fish-Tail Burner with Tip Protector (protects the flame from wind) and in fact everything that a perfect lamp ought to have.

Come back from the dark age of candles and use the light of the JUSTRITE. We can help you save big money. Write us

**Justrite Manufacturing Company**  
2075 Southport Ave. Dept. M Chicago, U. S. A.

### SEAMLESS ALUMINUM

No. 110

Made of 1/4-inch Seamless Aluminum—6-hour capacity. Reflector is part of the lamp; cannot be broken off. Equipped with steel ball and hook and has large screw threads for fastening the top and bottom together. It is wonderfully simple, sturdily constructed and easy to operate. Has only a few extra parts which makes the maintenance cost much less than other large lamps.

## Krogh Sand Pumps are lower in first cost and in maintenance than others—

Krogh Lined Sand Pumps will give you greater satisfaction for the very good reason that, compared with any other pump of equal efficiency, they are much lower in first cost and in upkeep expense. Other pumps of equal price cannot equal Krogh Lined Sand Pumps in work or in low operating cost.

Simple, sturdy, and with common sense built into every part, these pumps are designed by men who know mining and milling conditions.

Notice, in the illustration, how the liners are easily removed and replaced. They are made from special chilled car-wheel iron, harder than steel, yet less costly; no through bolts used to hold the liners in place.

Regularly made in 2", 3", 4", 6", and 8" sizes; special types designed to meet extraordinary conditions.

We shall be glad to mail you descriptive Bulletin No. M-79 or other bulletins describing Krogh Sinking Pump, Krogh Horizontal and Vertical Automatic Centrifugal Pump, Horizontal Motor Driven Pump, Krogh Dredge Pump, Krogh High Pressure Centrifugal Pump—write.

# Sullivan Drill Sharpeners

## FOR HOLLOW DRILL STEEL

Sullivan Sharpeners are particularly adapted for working hollow steel—

1. The heat required is short and does not close the hole. No danger of burning.
2. The method of dollying keeps the hole well opened, making a long hole. No danger of splitting.
3. The gripping dies hold the bit or shank in perfect alignment with the dolly pin, so that the hole is in the exact center of the steel.
4. The hammer process permits slow or fast, light or heavy blows to be delivered at will, assuring careful handling.

Described in Bulletin 1372.

The photo shows the Sullivan Sharpener at the Republic Mine, Cleveland Cliffs Iron Co., Republic, Michigan.

1 $\frac{1}{8}$  in. round hollow steel is used, with 4-point bits. A day's work is 500 bits, but on a consecutive run, 400 bits have been made in 4 hrs. 15 min. by the smith and one helper, who did the heating.

# The Sauerman Dragline Cableway Excavator

During the past seven years it has been on the market has demonstrated its high efficiency and great economy of operation.

Among the many uses of this machine in excavating work has been that of excavating and conveying material in wet and dry placers, reclaiming mine tailings, reclaiming ore from storage piles, etc.

Low cost of operation has been made possible with this excavator by the elimination of intermediate labor and machinery between pit and plant.

The entire operation of **Digging, Conveying, Elevating, and Pumping** is accomplished by **one machine** operated by **one man**.

Put your problem up to us and we will advise you. No obligations. Catalog on request.

**SAUERMAN BROS., 1141 Monadnock Blk., CHICAGO, ILL.**

**T**HIS book will be sent gratis to any truck user if the request is made on his business letter head and signed by a responsible official.

*White Trucks predominate in this country in total number of trucks in actual service—regardless of price.*

## A GRAPHIC RECORD of WHITE TRUCK PREDOMINANCE

**T**HIS new White Truck Book is the largest and most comprehensive catalogue of truck installations in this country—virtually an official Handbook or Directory of truck uses in all lines of industry and commerce.

It illustrates over fourteen hundred separate truck units, with a wide variety of bodies classified and grouped for each line of business represented.

Body designs and equipment are shown for both standard and special uses, embracing the entire field of truck operation, from the massive dump body to the finest delivery vehicle.

### THE WHITE COMPANY

CLEVELAND, OHIO

**UNITED  
FILTERS**

**T**HE UNITED FILTERS is organized for the purpose of establishing selling service.

The United Filters is sole owner of all patents covering the Kelly Filter Press, the Sweetland Filter Press, and the American Continuous Suction Filter.

We maintain extensive laboratory equipment where filtration tests are made and will gladly assist you with your filtration problems.

Our organization includes a complete consultation staff composed of engineers and chemists who have been for years successfully engaged in solving the many vexatious problems in filtration which are now confronting modern industries.

Hundreds of United Filters are in use in large progressive plants where economy counts.

---

## Special Filters

We build lead-lined filters for acid solutions: copper and wood-lined filters and many other special types used in the Sugar, Chemical, Metallurgical, Color, and Oil Industries.

**UNITED  
FILTERS**

### **Sweetland Self-Dumping Filter**

Because of special sluicing mechanism it is especially suited to handling materials which form a cake that is difficult to remove from the filter leaves. Can be readily constructed to permit handling acid or caustic solutions. Combines a maximum of filter area with minimum of floor space.

### **American Continuous Vacuum Filter**

#### **Type A**

The ultimate word in Continuous Vacuum Filtration. Recommended for dewatering of concentrates, for filtration and washing of all cake building mixtures that are easy to filter and where heat losses do not have to be taken into consideration. Particularly adapted to filtration of saccharate cake in Steffens Houses.

### **The Kelly Twin Unit**

Particularly adapted to the filtration of all liquors and pulps that yield a cake that is difficult to wash. Positive pressure insured, thorough replacement wash, and by drying with compressed air remarkably low cake moistures can be obtained. Shells can be readily insulated with asbestos, making it an ideal filter for hot solutions.

FILERS**

# 'TIMBER FRAMING'

By H. D. DEWELL, C. E.

275 PAGES, FULLY ILLUSTRATED. PRICE POSTPAID, \$2

This book, just completed by one of the foremost structural engineers and designers, covers the subject of Timber Framing completely for the first time.

Mine managers and engineers are frequently called upon to design and build surface-structures at mines, ore-bins, mills, head-frames, trestles, flumes, and other structures. It is desirable that the structures be as simple in design as possible, while meeting the demand for safety and efficiency. There is a very common lack of the appreciation of the strength of timber-structures properly framed, and this results in much unnecessary expense and waste of materials by building a structure in which the timbers are of far greater size than the condition demands. By knowing how, the designer builds neither too expensively, nor is his structure weak. It is for the determination of these questions that 'Timber Framing' will be of great value.

IT CONTAINS: Rules for Grading Lumber—Unit Stresses of Tension, Compression, Shear and Bending—Coordination of Tests—Truss Detail and End Connections—Nailed, Screwed and Bolted Joints—Intermediate Joints and Tension Splices—Foundation, and Columns and Connections—Design and Construction of Head-frames, Flumes, Ore-bins and Mill Buildings, Specifications for Timber Framing.

Get this book at a special reduced price with a year's subscription to the MINING and Scientific PRESS.

## The Only Modern Timber Framing Book Published

For a limited time 'Timber Framing' will be sent in combination with a year's subscription to MINING and Scientific PRESS, either on new subscriptions or renewals, for \$5.00. Use the coupon.

A Complete Mine Power Plant

## HILL AUTOMATIC HYDRAULIC AIR COMPRESSOR

**Delivers 50% more compressed air at the point of use than the ordinary combination of water wheel and compressor using same water power.**

This powerful automatic compressor is a complete mine power plant all in one machine—and it operates continuously, day and night, without watching. Requires no technical knowledge to operate.

### Engineer's Talk No. 4

The inherent power in the water is applied in the Hill Air Compressor by using the surge effect or semi-ram action. During the first part of the stroke the water column gains speed and stores up energy, and during the latter part of the compression stroke the moving weight of water is retarded and returns the energy stored up in the first part of the stroke. The velocity of the water in the pipe line constantly changes, but the flow never stops entirely. The longer the pipe line used, the smaller the change of velocity of the water. The machine compresses a volume of free air equal to the amount of the water used.

From a comparative initial and ultimate cost this compressor is the most economical manufactured.

**MAIL  
COUPON  
FOR  
INFORMATION**

Easy to install, light in weight, economical. Six sizes to fit all requirements, from small prospecting outfit, that may be mule-backed, to larger machines for the biggest properties.

## WESTERN DEPARTMENT

SECOND, OFFICERS' TRAINING CAMP, AUGUST 27 - NOVEMBER 26, 1917  
THE PRESIDIO, SAN FRANCISCO, CAL.

### GENERAL PLAN

To provide officers for the drafted forces of the National Army the War Department has adopted the policy of commissioning all new officers of the line (Infantry, Cavalry, Field and Coast Artillery) purely on the basis of demonstrated ability after three months' observation and training in the Officers' Training Camps.

*A second series of Officers' Training Camps will be held beginning August 27th, 1917, with the definite mission of producing a body of line officers (Infantry, Cavalry, Field and Coast Artillery) capable of filling all places in the grades above lieutenant and many of the places in the grade of lieutenant in the second 500,000 troops.*

### DATE AND LOCATION OF CAMP

The second Camp for the Western Department will be held at the Presidio Reservation, San Francisco, Cal., and will open on August 27th, 1917, and close November 26th, 1917.

### QUALIFICATIONS

#### Classes eligible to Apply. Age limits

(a) Members of the Officers' Reserve Corps (line sections) who, through no fault of their own, were unable to attend the first series of camps; also Reserve Officers of Staff Corps under 50 years of age with at least two months' service in war and who have had experience in Infantry, Cavalry or Artillery.

(b) Non-commissioned officers of the Regular Army recommended in March, 1917, for temporary appointment in case of war, and who, through no fault of their own, were unable to attend the training schools for Regular Army non-commissioned officers in April 1917. Maximum age limit 50 years.

(c) Resigned officers of the Regular Army. Maximum age limit 50 years.

(d) Men of proper qualifications made eligible for the Officers' Reserve Corps by the Army Appropriation of May 12, 1917. Maximum age limit 50 years.

(e) Men who have qualified for commissions under General Orders No. 42, War Department, 1915. Maximum age limit 50 years.

(f) Citizens of the United States who have had war service in the present war as officers or non-commissioned officers of the line in the armies of allied Powers. Maximum age limit 44 years.

(g) Men of exceptional qualifications who tendered their services to the Government prior to June 5, 1917, and who have been listed under G. O. 37, War Department. Maximum age limit 50 years.

(h) Citizens with valuable military experience and adaptability for commissioned grade, or citizens who have demonstrated marked ability and capacity for leadership, and are clearly adapted for military service in commissioned grade. Maximum age limit 44 years.

Employees of the United States must inclose the signed recommendation and consent of their chiefs.

NOTE.—Men who applied for the first series of camps must re-apply whether or not certified as suitable for the first camps. They will have no preference in selection for these camps but will be on an equal basis with other applicants.

*The minimum age limit for all applicants is 20 years and 9 months. However, in order to obtain the experienced class of men desired, preference will be given to men over 31 years of age, other things being equal. Because of the anticipated large number of applicants, it will probably be difficult for men under that age to qualify except in instances where the applicant has pre-eminent qualifications or unusual military experience.*

### NO LETTERS OF RECOMMENDATION

Note particularly that letters of recommendation are not wanted, but only the names of three responsible citizens who

know the applicant best. Each applicant must be examined physically at his own expense by a reputable physician who will fill out the physical report forming part of the official application blank. This preliminary examination is subject to review and the examining officer may require another examination. Men who submitted physical examination on the Army blank for the first series of camps may submit these reports in lieu of a new examination.

Applications will be received up to July 15, 1917. Under no circumstances will an application be considered if received after July 15.

### OBLIGATION

Accepted applicants, unless they are reserve officers or members of the Regular Army or National Guard in Federal Service, will be required to enlist for a period of three months, under Section 54, National Defense Act, and will agree to accept such commission in the Army of the United States as may be tendered by the Secretary of War. The enlistment obligates one to service in the training camp only.

### PAY AND EXPENSES

The Government will pay the men in training \$100 per month during the three months' course and will provide transportation, uniforms and subsistence except that Reserve Officers in training will receive the pay of their grades and will provide uniforms and subsistence at their own expense.

### CHARACTER OF MEN DESIRED

Since the special object of these camps is to train a body of men fitted to fill the more responsible positions of command in the new armies, every effort will be made to select men of exceptional character and proved ability in their various occupations. While it is desired to give full opportunity for all eligible citizens to apply, no man need make application whose record is not in all respects above reproach and who does not possess the fundamental characteristics necessary to inspire respect and confidence.

### HOW TO MAKE APPLICATION

Every candidate must file his application in person with the Local Committee of the Military Training Camps Association in the town in which he resides. A Military Training Camps Association Committee will be appointed in every town having a population of not less than 2500 within the eight states from which candidates are to be drawn for the Presidio Camp. From these Committees application blanks can be secured. Information as to the identity and address of the above mentioned Local Committee can be had from the cashier of any bank. Do not mail your application.

The headquarters of the Military Training Camps Association for the Western Department can be addressed below.

P. M. LANSDALE,  
Executive Secretary,

Military Training Camps Association of the  
United States. Western Department,  
201 Pine Street, San Francisco, Cal.

June 25th, 1917.

## Speed up with Electric Power

*G-E Equipment is reliable and economical*

**H**ERE are some of the ways in which modern industry has been speeded up by putting electric power to work in the right place.

Metal mines have boosted output to meet world-wide demands. Great central power plants in place of small local plants in coal mining areas now supply cheaper electric power per ton output for each mine. All tonnage records have been smashed in the steel industry. Greater automobile output has lowered prices and given better road transportation. More and better cloth has been produced at lower power costs.

The engineering problems solved in putting electric power to work in these and other industries were many and intricate. Production of electrical equipment suited to this work and in quantities required is an important part of this company's service to American industries.

Any problem involving the use of power can be simplified by the application of electricity. The General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to co-operate with manufacturers and engineers in every possible way.

# EDITORIAL

T. A. RICKARD, Editor

**A**TENTION is directed to the sub-heading on our cover-page. Some readers may not have noticed it. We are glad to be able to assert that this is "an independent paper, owned, edited, and managed by engineers."

**O**UR British friend *The Mining Magazine* informs us that the Board of Inland Revenue has been induced to regard a mine as a wasting asset, and in accordance with this decision some allowance for amortization of capital will be made in connection with the assessment for the excess-profit tax. Thus the British tax-collector has learned a fundamental truth. War is an effective teacher of economics.

**N**ITRIC ACID to the extent of 7000 tons per annum will be manufactured at a new plant being erected at Trollhättan, Sweden. The Birkeland-Eyde process will be employed. The new company is being financed in part by Germans, and the output, naturally, will be utilized in the manufacture of explosives, some of which will likely be directed to the destruction of Americans. This brings home to us anew the impossible position of a nation pretending neutrality in a world-racking war.

**F**ROM New York it is reported that the Government has placed an order for 60,000,000 pounds of copper at 25 cents per pound. Meanwhile arrangements are being made for a much larger contract at a price not yet determined. There is talk of higher market quotations owing to the curtailment of output at the mines due to labor troubles, but any rise at this time would only give aid to the labor agitator and draw attention to the artificial methods by which the high price of copper is maintained.

**N**EWs comes from London that the Giant mine, in Rhodesia, has been closed because "there is no hope of running the property at a profit." This sepulchral announcement may be compared with the recklessly optimistic statements that sent the shares of the Giant to \$32.50 in 1909, giving the mine a valuation at that time of \$8,500,000. Only \$5 per share has been paid in dividends since then. This was one of the mines that brought discredit not so much on Rhodesia as upon Rhodesian finance, and more particularly on the stock-jobbing methods of the Consolidated Gold Fields of South Africa.

**T**UNNEL-DRIVING at Pine Mountain is the subject of a highly informing article in this issue, written by Mr. H. Devereux. It will interest every engineer to

follow the close analysis of detail given to show in what manner, during this period of high costs, Mr. M. M. O'Shaughnessy, the engineer in charge, succeeded in driving and lining an 8700-ft. tunnel, with a section of 8 by 8 feet inside the timbers, at the average rate of 19 feet per diem and at a total cost per foot of \$16.12. Interesting comparisons with adits driven by the Alaska-Gastineau Mining Company, the Arizona Copper Company, and others form a measure of the successful work accomplished at Pine Mountain.

**F**ERRO-MANGANESE requirements in this country for the remainder of the current year have been subjected to critical analysis by *The Iron Age*, which shows, first, that a steel output in 1917 of 45,000,000 tons almost certainly will be realized. This would be an increase of 45% over the production in 1913. Of that total, 40,320,000 tons would require ferro-manganese at the average rate of 17 pounds per ton of steel, indicating 306,000 long tons of ferro-manganese required. To meet that demand the calculated output of our own furnaces is 240,000 tons, and the anticipated imports will add 70,000, making a total of 310,000 tons. Any decrease in the productivity of foreign mines would easily produce a shortage. It is important to investigate further the possibilities of developing domestic deposits, in conjunction with concentration to meet the market standard.

**C**IRCULARS have been issued from the head office of the American Institute of Mining Engineers for the purpose of eliciting opinions in regard to a new definition of eligibility for membership. We note, with pleasure, that no attempt is to be made to disturb the status of those already members. Some years ago sundry reactionary members suggested the idea of creating a special class of superior persons to be called 'Fellows', who were to be placed on a plane above the run-of-mine 'Members'. That would, we hope, have provoked a riot, for once a man is a full member of a society he has a right to object to any later sorting and stratification. The plan now proposed is something quite different; it is to render the election of members more selective and so automatically to improve the average of the whole membership, making the Institute more truly representative of the profession.

**R**ECENTLY one of our readers wrote to protest, vigorously, against the use of pounds, shillings, and pence, instead of American currency, in an article on mining in South Africa. It annoyed him. We replied that the rate of exchange between pounds and dollars

had ranged from \$7 to \$4.60 during the last three years and that it might vary considerably between the date of writing an article and the date of publication. The same holds true for Mexican economies; who shall state the equivalent—in cents—of the peso at a given moment? Uniformity is admirable, but it may be the cause of confusion. The article to which our protestant referred was written by an American mining engineer, Mr. H. Foster Bain, and it was intended for the reading, among others, of American engineers on the Rand. They would have been annoyed, at least as much as our kicker, if we had given them our criticisms, through Mr. Bain, in terms of dollars and cents. Gentlemen, think of the other fellow sometimes.

WE publish a short statement issued by the National Research Council concerning submarines and their capabilities. This summary of facts is intended to guide inventors and engineers now at work in devising a means to overcome the assassin of the seas. Most of the ideas transmitted to Washington emanate from fanatics. Mr. Lawrence Addicks confessed recently that the Naval Consulting Board, of which he is a member, is "overwhelmed with people who have fantastic ideas of hanging nets and magnets on ships to stop torpedoes." We feel confident that an invitation for suggestions from our engineering friends will not add to the burdens of those at Washington, but that any ideas presented by them will be sane and scientific. The submarine is still a menace. We must find some way of circumventing it. Vice-Admiral Sims, now in command of our destroyer flotilla on the other side, has laid emphasis on the fact that the submarine must come to the surface at intervals to breathe, as it were, or, more technically, to recharge its batteries. That requires from three to five hours. It is then that the patrol-boats have a chance to hunt their quarry. The nets used to entrap a submarine when moving under water are made of steel wire a quarter of an inch thick in meshes 12 feet wide. Already the Germans have invented a tool to cut such nets; therefore it remains for us to devise a kind of net that they cannot cut in the limited time available. Mr. Arthur H. Pollen, a British naval expert of high standing, advocates an active search for submarine bases and the destroying of them. Unfortunately the Germans use neutral coasts, such as those of Spain and Norway, as a rendezvous, and until these neutrals join us it will be impossible to carry out such a policy with any degree of completeness. Rear-Admiral Goodrich, writing in *The Nation*, advocates this same idea of tracking the enemy to his lair. The stretching of a steel net from Scotland to Norway, across 240 miles of shallow water, has been suggested as a costly but feasible means of defence, the idea being based on the successful use of similar netting for protecting traffic from England to France. Such fine and large schemes are less likely to prove effective than the research now being made into means for detecting the submarine by sound or exposing it to attack by light. Once the secrecy of the submarine's movements has been pierced its power

for harm will be enormously decreased. The only idea that ever came to us on the subject was to use oil to cover the surface of the sea and thereby obscure vision through the periscope, but we decided that we would not bother our friends on the Naval Consulting Board with such a proposal, because the ocean is wide and oil is costly. At one time the aeroplane, more particularly the hydroplane, was expected to ferret the marine vermin, but apparently this method of hunting has proved disappointing. It is too much like looking for a needle in a haystack. A vigilant patrol by small boats supplemented by destroyers appears to be the one sure method. It is a great and honorable sport in which thousands of gallant men are now engaged. Meanwhile it is incumbent upon American ingenuity to devise something more directly effective.

## Labor Unrest

Work is being stopped at the copper mines of Montana and Arizona. At Butte, a strike, started by the Metal Miners Union, has spread among the electrical workers, crippling the operation of the mines to a point where the entire local industry is paralyzed. In Arizona the strike at Jerome had no sooner been adjusted than demands were made upon the companies operating in the Clifton-Morenci district, where a bitter strike was ended only a year ago. Serious trouble has developed at Globe, Miami, and Bisbee. Apparently the labor population of a number of important mining districts is seething with unrest, and unless some measure of patriotic spirit is shown on both sides the supply of copper will be seriously diminished. We have received copies of the bulletins issued by the strikers at Butte. They are written intelligently and forcibly. We have also received a copy of the *Arizona Labor Journal* containing a statement by Mr. J. L. Donnelly, president of the Arizona State Federation of Labor. This also is a clever brief for the workers. The demand for higher wages, despite the drop in the price of copper, is based upon the increased cost of living. For instance, Mr. Donnelly claims that "\$3.50 per day eighteen months ago would purchase the equivalent of \$5.50 today." Even if this be a slight exaggeration, it is more than likely that the taste for luxury excited by the sudden rise in wages has caused the miner to be so reckless in his purchasing that today he is saving less than he did eighteen months ago. Our own recent observations of life in several mining districts would tend to confirm this inference. The copper-mining companies made a great blunder, of course, in not paying the bonus separately from the wages; they should have given the regular pay in one check and the bonus, based on the rise in the price of copper, in another check. That would have reminded the men of the temporary nature of the big advance in their income. But, say the leaders of organized labor, the increased pay, even with the bonus, is not enough, now that the cost of living has advanced faster than the bonus dependent upon the price of copper. Copper may have fallen in price, they say, but it is still

selling at a figure more than twice the cost of producing it; the companies are making enormous profits; we are not profiting at all, owing to the high cost of living; so we demand another increase of wages. Not content with that the Arizonan unions insist that the contract system shall be abandoned, and they even murmur something about a 6-hour day. Here bad faith becomes manifest; for these further demands have nothing to do with the high cost of living and are merely clubs shaken at the managers with the idea of intimidating them. At Butte the demand for higher wages, based on vital conditions, is tied to a protest against the 'rustling card,' meaning the exercise of discrimination by the companies in giving employment. Protest is also made against the unsafe conditions underground, this last being prompted by the recent Speculator disaster. If the loss of life was due, as is asserted, to the existence of concrete bulkheads that blocked the necessary exits, then the men have a legitimate grievance not only against the companies but against the State Mine Inspector; but the charge of black-listing means merely that the employer tries to keep out men that are known to be trouble-makers. Of the secondary issues, the contract system is much the most important because it goes to the root of the question whether the employer is to have a fair deal; whether he is to pay for what service he gets, or whether he must distribute uniformly high wages for a varying return in work, giving equal pay to the incompetent and the competent, the lazy and the energetic among his employees. We believe that the contract system is fair to all concerned and the only system that upholds the self-respect of the working-man; we recognize, however, that it is not always fairly applied and that it then becomes vicious. Here we come to the root of the whole matter: fair dealing as between men. We sympathize sincerely with the managers of mines, for they are often placed between the devil of the greedy capitalist and the deep sea of the workman's ignorance; it needs—always—a man of strong character and high principle to safeguard the interests of a company and yet protect the welfare of the men on the pay-roll. The mining profession as a whole is more than willing to be fair to the toilers underground, and its keen interest in the welfare movement is an indication of that fact, so that the use of the high cost of living as an argument for higher pay would be received sympathetically if it did not come on top of a period of extravagance in the mining communities and if it were not made at such a time and in such a manner as to suggest a 'hold-up.' The strike bulletin at Butte exclaims joyously that the companies cannot furnish metal to fulfill their contracts now that so many men are idle. Who will suffer? The companies? No! The Nation; the Great Cause to which we are committed; these are the ones to suffer, and when the public awakens to this fact we expect to see a popular demand for a speedy settlement of this sinister attempt to clog the wheels of industry at a period of great crisis. Thus we started with unconcealed sympathy for the predicament in which economic conditions, due to the War, had placed the miner and his

comrades, but we arrive inevitably at the conclusion that sympathy must be withheld if advantage is to be taken of the Nation's necessity in order not only to obtain a reasonable concession but to enforce an unreasonable demand. One word more. We have referred to the propaganda of union labor. It is well prepared and likely to be effective. The labor element is organized and articulate. The employers, namely, the mining companies and the resident managers for the companies, are deficient in these two respects. Only too often petty jealousies interfere with united action and the differences of policy prevent an outspoken statement of purpose. We believe that the companies should take the public into their confidence, for, in the end, public opinion is the arbiter, just as public opinion is the power behind the law. The propaganda of the labor agitators should be met with a frank explanation of the case as it seems to the mine managers, and the explanation ought to be put in printed form so that everybody in the mining community can read it. In some localities the companies control one or more local papers; they should acknowledge the fact frankly so that the control may lose any sinister suggestiveness. Nobody thinks it improper for the union to run a paper. Let both sides come into the open and argue their contentions at the bar of public opinion. This is a democracy. The methods of the Star Chamber and those of the Black Hand are equally repugnant to good citizens. Publicity is the anti-toxin of wrong.

## Misgoverned Mexico

Mexico is testing our mettle. The wholesale confiscation of Mexican mines owned by citizens of this country may be regarded as a deliberate challenge. Abandonment of the copper mines and smelters at Cananea has been forced by executive orders with which it was impossible for the owners to comply. At the same time the Department of Finance in Mexico City is proceeding to confiscate 7702 mining claims belonging to the Cananea company on the ground of its refusal to re-pay taxes that had been paid once to other officials, but which the Carranza administration insists must be forthcoming again, with extravagant penalties accrued under arbitrary decrees skilfully contrived to work the ruin of alien investors. The plain logic of the situation is ignored. For years no constitutional government has existed in Mexico. Carranza was not in line of succession to the presidency after the forced resignation of Madero. He had no legal status as a Federal officer under the constitution of 1857. He took up arms ostensibly to re-instate a government that would adhere to the terms of that constitution, and he was entitled to the credit of good intentions while he continued to pursue that purpose. Nevertheless, this did not entitle him to revenue from such Mexican territory as he did not effectively hold and administer. Administration involves protection, and the Cananea company was not protected by Carranza while it was being robbed by Maytorena's looters. Moreover, Maytorena had a sounder title to executive authority in

Sonora than Carranza, because he was actually there, and he was likewise in arms professedly for the re-establishment of a stable government under the old constitution. He had declined to co-operate with the First Chief for reasons that were honorable. In the meantime, the question of the right to rule and to collect duties and taxes was being rudely discussed on the battle-field. It is preposterous for Carranza to claim that he represents a government that has suffered by loss of the revenues wrested by officers in control before he had established his authority. The United States has treaties with the government created under the constitution of 1857, and those treaties concede no right to penalize American property-owners for having paid moneys under duress to revolutionary upstarts. Carranza does not represent the Mexico of the old constitution with which we entered into treaty-relations, for he did not re-establish that constitution; he evaded it while acting as dictator, and he ended by discarding it altogether and framing a new constitution, written with intent to win the adherence of the rabble by means of labor-clauses that express the principles of the I. W. W., while it reserves powers to the executive that make him in effect an autocrat. Such an international situation has been created by these confiscatory acts of the Carranza government as to call for more astute diplomacy on our part than has characterized our previous dealings with revolutionary Mexico.

Not only has Cananea suffered, but the El Tigre silver mine, belonging to the Lucky Tiger-Combination Company, has been obliged to close, as well as the rich Pedrazzini silver property near Arizpe, at which point the manager, an Englishman, has been placed in confinement. It is not the mines alone that have suffered. The important agricultural project in the Yaqui valley, belonging to the Richardson Construction Company, in which Messrs. John Hays Hammond and Harry Payne Whitney are the chief shareholders, has been seized by the Mexican officials for refusal to pay confiscatory taxes and to comply with impossible regulations. This form of Turkish justice is being administered to corporations belonging exclusively to non-Teutonic Americans whose properties lie comparatively near the border. While arbitrary proceedings have hampered and oppressed foreign corporations operating elsewhere in the republic, the most conspicuous violations of alien rights have taken place where they would attract the most attention in the United States. This implies an ulterior motive. It is clearly meant to ascertain the strength and decision of the United States in the first instance; to see whether in the face of the German peril we dare risk hostilities with Mexico. We know, and Carranza knows, that a war with him would ultimately absorb more soldiers than we now have trained and ready. If we hesitate, if we fail to send an ultimatum that would involve armed intervention in case of a diplomatic rebuff, he will be emboldened to increase the embarrassments and financial burdens of the oil-producers. Evidently he is feeling us out under the direction of his German advisors. Meanwhile he is

preparing for aggressive action by rushing the construction of new munition-plants furnished by the Japanese. The latest of these is being erected near the City of Mexico. If we continue our time-worn policy of reasoning and coaxing he may be indiscreet enough to undertake to prohibit the exportation of oil. That is what his new-found friends desire. It might wreck Mexico, but Mexico could also wreck the oilfields before the Allied fleets could take possession. It is even possible that the marines could not cope with the situation, and the interruption of oil-deliveries for a few weeks might imperil the operation of the British fleet. We ought to take drastic action. We have on hand the business of crushing the Enemy, and he who is not with us is against us. Carranza is not only not with us, but by every act and word he has shown himself hostile; nevertheless, he understands plain English when spoken in no uncertain tone. He does not wish to be dealt with as we and his own people will deal with him if he falls from power in a clash with us. He is less loved even than Santa Ana, and would less easily resist the general opprobrium that would follow an unnecessary and calamitous conflict with the United States. Had he played fair with Villa he might have ridden into power with the support of all classes remaining in Mexico, and he would not at the present time be defied by Zapata in Morelos, by Felix Diaz in Puebla, by Meixueiro in Oaxaca, by Villa and Salazar in Chihuahua, and by the brothers Cedillo in San Luis Potosí. Had he played fair with the United States and respected the treaty-rights of our citizens such a flood of American capital would have poured across the Rio Grande to develop the resources of that marvelous store-house of mineral riches that he would not now be floundering in financial quagmires, nor would he have had to resort to the looting of the Mexican banks in a last desperate effort to retain the loyalty of his soldiers by paying them with specie that should have been jealously guarded in the interest of the banking-credit of the country. Evidently the question now before him is whether he can borrow from the United States to keep himself going, or whether, failing in this, he can so cripple us and our Allies as to promote the triumph of Prussianism. Germany cannot finance him at the moment; we can if we will; and, being a shrewd man, he is naturally weighing the chances of ready American coin against Teutonic promises to pay him if he turns the trick. If we finance him once we shall have to administer the same medicine repeatedly. It is for this country to decide whether to pay tribute to Carranza or, if he prove recalcitrant, whether the hour be propitious for putting some worthy Mexican in power charged to maintain a respectable and self-respecting government. We do not want Mexico; we merely desire a decent administration in Mexico, representative of the finer intelligence and spirit of the republic and true to its constitution. We believe there are men in Mexico as capable of bringing this about as were Mitre and Sarmiento in Argentina, whose courage and wisdom started that country on its triumphant career of genuinely democratic progress.

# DISCUSSION

*Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.*

## Sampling Large Low-Grade Orebodies

The Editor:

Sir—This matter seems to have reduced itself to the question as to whether such bodies can be better sampled by mill-tests or by ordinary moil-sampling, and anent this you ask several pertinent questions in your issue of May 26.

I believe Mr. L. A. Parsons has struck the keynote when he says: "representative—that is the crucial point." If mill-tests could be made representative of the ore-blocks or of the mine from which they are taken, I believe the results arrived at would in many cases be nearer the correct value than that obtained by moil-sampling, but this necessitates a large number of mill-tests from any given block of ore, in a wide deposit, and a great number of such tests from the various cross-cuts, drifts, and raises, that so frequently expose but two of three sides of a block.

In order therefore to make a mill test 'representative' there must be at least several hundred, perhaps a thousand, of them, each a separate run with a separate clean-up. Has any one ever heard of such a thing having been done? Yet in the examination of large ore deposits by moil-sampling it is a common thing to take anywhere from 1500 to 3000 samples, while during the exploration and development of the low-grade copper deposits the number of small samples derived from both drilling and moiling runs into the tens of thousands.

It is evident then that the small-sample method has and always will prevail over the mill-test, chiefly because it is far more 'representative' of the ore-mass. In either case when the deposit is a large one an enormous amount of development work is required, involving heavy cost. If to this be added the far greater expense, as compared with moil-sampling, of cutting hundreds of small stopes and making an individual test on each lot of ore the preliminary outlay is too great to be practicable.

In some of the large deposits of low-grade gold ore even the development work necessary to expose enough faces to make moil-sampling fairly 'representative' has not been done, not only because of the great expense involved but because the resultant work cannot be used in the subsequent ore extraction on account of the mine having to be worked in huge stopes of unusual height, in order to reduce the cost of mining.

In the case you refer to where 375,000 tons of ore were milled before the value of the ore was considered to be established, most of us, I think, would have considered the mining and milling of such a huge amount to have

been a 'representative' test of the mine. But subsequent results have shown that it was not, and the natural conclusion is that driving, cross-cutting, etc., on several levels and for long distances would have paid in the end. It is easy to be wise after the event, but I think this experience should teach one the almost insuperable difficulties in sampling a large and very low-grade mass of gold ore. As Mr. Jackling has pointed out, the expense involved makes it impracticable financially.

Again, we have all met the mine-owner who says, "This mine cannot be sampled; only a mill-run will give you accurate and dependable values." Such a mine is almost sure to be a good mine—for the owner to keep.

Moil-sampling, done with care and judgment, can and should be more 'representative' of the ore behind the sample, because of the greater number of samples that can be taken, because of the greater elasticity of the method where the metal contents occur in streaks and patches, because the method is readily applicable to remote places and workings more difficult of access, and because it is far cheaper than mill-tests made in sufficient numbers to make them 'representative.'

After all, what is the sampling of a mine other than a means of obtaining "the best possible approximation" of its value. In the nature of the case it can only be an approximation due to several causes into which it is not necessary to enter here. Enough to say that no perfect sampling method has yet been advised. That moil-sampling comes closest to this "best possible approximation" has, I think, been definitely proved by practical experience.

New York, June 20.

THOS. H. LEGGETT.

## Forest Reserve Again

The Editor:

Sir—I send you an open letter addressed to H. G. Merrill, supervisor of the Monterey National Forest Reserve, King City, California, revealing a situation that is detrimental to operators of mines on Forest Reserves. It is a subject that deserves attention. The letter follows: Mr. H. G. Merrill, King City, California.

Dear Sir: I would respectfully call your attention to the following facts: Since 1906 annually the officers of the reserve have caused to be issued grazing permits for the section of country known as 'Gold Ridge', which is private property, being located as mineral land. The stock is turned loose without herders, fences, or corrals, with the result that they destroy the trails, roads, ditches, and reservoirs every year, that have been built at great

expense. It is impossible to make headway without protection against the above acts. We have protested in vain to the officers; and the Government is practising the same method, in that they sued Messrs. Shannon and Little for the State of Montana and Colorado. The county of Monterey passed the 'no fence' law to check the very acts that the officers of the reserve are committing. You leave us no feed upon our own ground for our stock to work our mine. The hue and cry now is, where has the prospector gone? He is not in evidence upon the public domain any more. Get the records in the case of U. S. v. Copper Mountain Mining Co., and study them well, and you won't ask the reason why. Never a forest ranger comes around to ascertain what damage is being done. You say in your USE BOOKS "we foster the small home-builder, mining not interfered with", and the like. The records here and in the Pinnacles and National Monument Reserve do not show it; it is the reverse. See the protest filed at Washington in the Interior Department against the unlawful acts of the above officers;; it will show how business has been done in the above reserves, and so far there has not been any redress. The above protest was filed by Wm. D. MacPhie, of Soledad, on behalf of the above copper company some 3½ years ago. For full particulars apply to the undersigned, at Gold Ridge.

HENRY F. MELVILLE.

Jolon, California, March 31.

The Editor:

Sir—Upon examining the records of this office I find that a similar protest to the one transmitted by Mr. Melville was filed on December 18, 1909, and that nearly each year since that date a similar protest has been submitted. Upon receipt of each one of these protests the local Forest officers have endeavored to make an adjustment between the mining claimants and the stockmen who grazed their stock under permit in that particular locality of the Monterey National Forest. From the records it appears that there are between 25 and 30 head of stock under permit in this locality, the owners of which own ranch property and grazing-land near the Forest. These permittees have occupied the Forest ever since its establishment and have gained what we term a preference in the use of National Forest range; however, our regulations provide specifically that subsisting mining locations are not taken into consideration when grazing permits are granted for National Forest land. I quote from our instructions to local Forest officers the following: "Mining claims—Persons holding unpatented mining claims within a National Forest have the right to the grass or other forage upon such claim needed for stock used in connection with the development of the claims, but they have no right to dispose of the forage to any other person or to collect rental for the use of the claims for grazing purposes. Such unperfected mining claims, therefore, cannot be accepted as the basis for a permit under this regulation." In view of the fact that we have no jurisdiction over these claims, and, further,

from the fact that the permit issued to each stockman states specifically that it does not grant the right to the use of any other than National Forest lands, you will see, I believe, that we have no jurisdiction in this matter, and if the damage done by the grazing of this stock actually occurs it is a matter that must be handled under the State law between the mining claimants and the owners of the stock. In the past we have endeavored to have all parties interested come to some agreement so that the proper drift-fences could be constructed, or other means devised by which this complaint would not be continually coming up. Our efforts along this line have been unsuccessful, and the only course left open for us to pursue is to withdraw from the controversy entirely and let the mining claimants and the owners of the stock adjust their differences.

C. E. RACHFORD,  
Assistant District Forester.

San Francisco, California, June 13.

## Canadian Mining Regulations

The Editor:

Sir—on March 5, 1917, under the provisions of the War Measures Act, 1914, the Canadian Government enacted, by order-in-council, certain regulations restricting the rights of aliens as to holding or acquiring, directly or indirectly, mining and other property in Canada; where such rights, lands, and so on, were vested in or administered by the Federal Government. As aliens who were not enemies of Canada were also included, mining men and others deemed the regulations too severe; therefore they induced the Government to rescind the objectionable clauses and substitute others bearing only on alien enemies, companies and corporations.

The revised order-in-council, No. 1268, is dated May 8, 1917, and a copy of the same is herewith enclosed.

As you published a summary of the regulations dated March 5, 1917, I hope you will be agreeable to give the same publicity to the revised copy now enclosed.

WM. THOMLINSON.

New Denver, B. C., June 20.

Clauses 3, 4, and 5 of the Regulations established by Order in Council of the 5th of March, 1917, (P.C. 572), are hereby rescinded and the following Clauses are hereby made and enacted in lieu thereof:

"3. No company shall acquire or hold any of the rights, powers or benefits hereinbefore referred to if such company be an alien enemy company, or registered in an alien enemy country, or having its principal place of business within such country, or if the chairman of such company or any of the directors are subjects of an alien enemy country, or if such company is controlled, either directly or indirectly, by an alien enemy or alien enemies, or by an alien enemy corporation or alien enemy corporations.

"4. Any alteration in the Memorandum of Articles of Association, or in the constitution, or in the laws of any company holding any rights, powers or benefits hereinafter referred to shall be reported by the proper officer of the company to the Minister of the Interior, and two months previous notice in writing shall be given to the Minister of the Interior of the

intention to make any alteration which might conceivably, either directly or indirectly, affect the character or control of any such company, and if, in the opinion of the Minister of the Interior, the said alteration shall be contrary to the cardinal principle that the said company shall be and remain a company not of alien enemy origin or control, the Minister of the Interior may refuse his consent to such alteration, and if his refusal is not obeyed, may declare such company to be an alien enemy company and may cancel the said rights, powers and benefits under the provisions of the next following regulation.

"5. If any company which has acquired any right, power or benefit hereinbefore referred to shall, at any time, become subject to the control of an alien enemy, or alien enemies, or an alien enemy corporation or corporations, or shall assign any of the rights, powers or benefits aforesaid, without the consent in writing of the Minister of the Interior being first had and obtained, or if the said right, power and benefit has been acquired through error, misrepresentation or fraud, the Minister of the Interior may cancel the grant of such right, power or benefit and thereupon the same shall *ipso facto* be cancelled and any moneys or fees paid to or deposited with His Majesty shall be *ipso facto* forfeited to His Majesty.

## Magmatic Ore Segregation

The Editor:

Sir—In view of a suggestive article by Dr. J. T. Singewald in the MINING & SCIENTIFIC PRESS for May 26, where the mode of occurrence of chromite is referred to, a review of the conditions under which chromite occurs in southern Quebec may be of interest. The examination of the Quebec chromite deposits has not yet been completed, and further investigation may throw new light on their origin. A preliminary report (Memoir 22, Geological Survey of Canada) covering this area was prepared by myself in 1911 and published in 1913. Since that date a topographic map of the district has been drawn and Dr. R. Harvie of the Geological Survey staff is preparing to make a final report. It is therefore suitable to confine this communication to an interim description, mainly of the features bearing on the subject of Singewald's article. The chromite-producing district of Quebec lies south-east of the St. Lawrence river, and is distant by rail about 80 miles from the City of Quebec and 160 miles from Montreal. The main production has been from a small area about 6 by 12 miles in extent, but other occurrences have been found outside of this area which, in the present favorable market, are being developed with good prospects of success. The production since 1886 has been somewhat more than 100,000 tons.

The ore occurs in a complex of basic igneous rocks, intrusive into folded and altered sediments consisting of slates and quartzites of Cambrian and Ordovician age. The principal types of igneous rock are peridotite partly altered to serpentine, pyroxenite, and diabase. Other allied rock-varieties appear in places as gabbro and porphyrite. Granite, also, is present in the form of dikes and small bosses. The basic rocks are plainly differentiates from a single intrusion, while the granite has been intruded later, though probably while the wall-rocks were still heated. The basic rocks occur in the form of stocks and of sills that in places show laccolithic thicken-

ing. The different rocks are arranged in the sills in the order of decreasing basicity and density, that is, peridotite, pyroxenite, and diabase, with the peridotite on the bottom, while in the stocks the order of basicity is from the centre outwards.

Chromite occurs widely, almost universally, disseminated throughout the peridotite and the pyroxenite as an accessory constituent. Microscopic evidence shows that it is a primary mineral and has been one of the earliest to crystallize in these rocks. It also occurs in masses, often forming single orebodies containing several thousand tons. These occur usually, if not only, in the transition-rock between the peridotite and pyroxenite. Without recounting the evidences at length, it may safely be said that the field-relations indicate that the orebodies are primary members of the igneous complex. The walls are frequently ill defined, irregular, and not bounded by structural features. There is no evidence adequate to prove either solution and re-deposition in masses of this difficultly soluble mineral, nor its injection in its present position after the solidification of the country-rock. Certain minerals denoting pneumatolytic action, such as garnet, vesuvianite, and molybdenite are found at some of the deposits, but they are associated with later granite dikes. In brief, the ore deposits seem to be phases of the rock in which they occur.

The place in the igneous complex in which the chromite occurs in mass, between peridotite and pyroxenite, is the principal point of interest. It neither agrees with the arrangement of the rocks of the complex in order of density, nor with its own place where disseminated as an accessory mineral in these rocks, in which it was one of the first minerals to crystallize. While chromite shows a strong tendency toward early crystallization, its maximum development seems to have taken place near the close of the period of crystallization of the olivine. This seems to imply a retarded crystallization of the chromite in mass, such as Singewald has noted in ilmenite and magnetite deposits, and which, with apparent good reason, he ascribes to the physical action of the mineralization agents of the French petrologists. Broadly speaking, the chromite-concentrations in Quebec seem to be best described as products of magmatic segregation occupying a position in the series of differentiates that has been influenced by the action of the mineralizers.

Montreal, June 9.

JOHN A. DRESSER.

MAGNETIC-IRON ores often contain large amounts of manganese; also many manganese deposits are mixtures of iron sesqui-oxide, or of limonite, with manganese dioxide. The iron in these can be removed, when not present in a pulverulent form, by various types of magnetic separators, such as the Wetherill. The residue containing the manganese can then be further concentrated, if necessary, to eliminate silicious minerals so as to bring the manganese product within the limits set by the makers of ferro-manganese, which are a minimum of 40% metallic manganese, and a maximum of 12% silica. Also the maximum permissible phosphorus content is 0.225%.

# Phosphate Rock

By R. W. STONE

\*Prior to 1914 the United States was producing annually close to 3,000,000 tons of phosphate rock, of which over 99% came from Florida, Tennessee, and South Carolina. With the beginning of the war the facilities for shipping phosphate rock to Europe were greatly decreased. Many Florida plants were shut down, and they have not resumed operations. In 1916 the industry was in some areas practically demoralized, but there was nevertheless a gain over 1915. The total output in 1916 was 1,980,000 tons, valued at \$5,897,000. Tennessee, in spite of decreased production, has yielded a larger proportion of the country's output since the War began. It would seem that the Tennessee industry, not having been so related to the export trade, and being equipped in part with modern machinery, should develop while the European trade is restricted and while the industry in Florida and South Carolina is more dormant. The deposits of phosphate rock in the United States are confined very definitely to the southeastern part of the country and to the Rocky mountain region from the latitude of Salt Lake City, Utah, to that of Helena, Montana. Although by far the largest deposits are in the Western States, the production from that region is less than 1% of the whole, owing to the lack of a nearby large market at present and to high freight rates on the crude rock. The western rock-phosphate deposits are so extensive that, even if the entire world depended on them for its supply, they would not be exhausted in many generations. The Florida phosphate deposits comprise three classes—hard rock, land pebble, and river pebble. The hard rock is the highest grade, the land pebble is produced in the largest quantity, and the river pebble is not mined at present. The area of hard-rock deposits forms a narrow strip along the western part of the Florida Peninsula from Suwannee county to Pasco county, a distance of approximately 100 miles. The land-pebble phosphate area lies east of Tampa and is about 30 miles long and 10 miles wide. The South Carolina output consists of land-rock phosphate mined in the vicinity of Charleston. River-pebble phosphate occurs in the same area but is not mined. The Tennessee deposits of rock phosphate are in the west-central part and extreme northeast corner of the State. The latter have not been mined. Three types are recognized and known by their colors as brown, blue, and white rock. The brown rock comes from Maury, Giles, Hickman, Lewis, and Sumner counties and is sold under a guaranty of 70 to 80% tricalcium phosphate. The blue rock is mined in Lewis and Maury counties and varies considerably in its phosphatic content. The phosphate deposits of Ken-

tucky lie between Frankfort and Lexington, and considerable quantities of rock have been mined near Wallace. Deposits occur interruptedly for a distance of 80 miles in the north-central part of Arkansas, and a small quantity is produced at Anderson, Independence county.

Four of the Western States possess vast deposits of high-grade rock phosphate, but the western production amounts to less than 5000 tons per year. Idaho, Utah, and Wyoming are the producers. Montana is not yet a producer, although at Elliston, Garrison, Philipsburg, and Melrose are extensive deposits easy of access and close to rail transportation. In the southeastern part of Idaho an extensive supply of high-grade phosphate occurs along both sides of Blackfoot river, in Fort Hall Indian Reservation, near Montpelier, and north of Bear lake. The Utah deposits are east of Great Salt lake, in the Wasatch and Uinta ranges, and east of Bear lake. These deposits are extensive, but the material averages only about 60% tricalcium phosphate. Western Wyoming also is rich in rock phosphate, the deposits being mostly in the Owl creek, Wind river, Gros Ventre, and Salt river ranges. Some of them are thick beds carrying 80% tricalcium phosphate and extending for many miles, and they constitute a reserve supply that is almost inexhaustible.

Estimated quantity of phosphate rock in the United States:

Eastern States:	Long tons
Florida .....	227,000,000
Tennessee .....	88,000,000
South Carolina .....	9,000,000
Kentucky .....	1,000,000
Arkansas .....	20,000,000
	345,000,000
Western States (Montana, Idaho, Utah, and Wyoming) .....	5,367,000,000
	5,712,000,000

Although the total reserves as shown by this estimate are extremely large, the supply of high-grade rock is much less and should not be considered inexhaustible.

While the War continues phosphate rock cannot be sent to the largest consumer, Germany, and high ocean-freight rates practically stop shipments to other European countries. The demand for sulphuric acid for making munitions has raised the prices of acid so that manufacturers of acid-phosphate have been obliged to curtail production. It seems reasonable to believe that at the end of the War European nations will need increased quantities of phosphate, as their stores of food-stuffs will be low, and intensive cultivation of the soil will be necessary.

# Principles of Flotation—I

By T. A. RICKARD

\*INTRODUCTION. The understanding of the principles governing flotation has been delayed mainly because the explanation of the phenomena—or appearances—characteristic of the process is to be found in physics rather than in chemistry. Modern metallurgy has been in the hands of men primarily chemists, rather than physicists. Cyanidation and chlorination, for example, may be explained by chemical formulas, even if they cannot be expressed in their entirety by the language of elemental symbols; but flotation is not to be interpreted in that way; it is controlled by physical laws that are obscure and that hardly came within the cognizance of the metallurgist until the need for study was felt by him within a period so recent that the full results of scientific research are not yet available.

To understand the rationale of the flotation process we must return to the amusements of our boyhood; in the soap-bubble and in the greased needle we shall find an inkling of the forces at play in the flotation machine. Everybody knows the trick of the greased needle. If a needle be greased and then placed carefully on the surface of tap-water in a bowl it will float, despite the fact that steel is eight times heavier than water. Even the natural oil on the fingers, or that obtainable by passing the fingers through the hair, will suffice for the purpose of assisting the needle to float.

The first idea is that the buoyant effect of the oil adhering to the needle prevents it from being drowned. However, the quantity of oil thus attached to the needle is not enough to buoy it; the specific gravity of the oil is, say, 0.9 as compared with water, which is the unit of specific gravity; therefore the flotative margin is only one-tenth, and for the oil to float a piece of steel, having a specific gravity of 8, its volume would have to be more than 80 times that of the steel. So the buoyancy of the oil does not do it. Moreover, an ungreased needle also will float. This experiment must be conducted carefully. To be certain that the needle was free from grease<sup>1</sup> I held it in metallic pincers, dipped it in a solution of washing-soda (sodium carbonate, which is a solvent for grease), and then dried it, taking care to use a clean cloth and not to touch it with my fingers. Then I placed a piece of tissue-paper on the water in a cup and laid the needle, held in the pincers, upon the paper, which was depressed gently into the water by the point of a wooden match, until the paper became soggy and finally sank, leaving

the needle floating. It lay in a depression of the water-surface, which appeared to be bent under it.

The needle that will float after being greased is larger than the one that floats without being greased,<sup>2</sup> so the oil seems to aid flotation; but when the needle is too large it cannot be made to float, greased or not. It is too

FIG. 1

heavy; that is, the force of gravity multiplied by mass is sufficient to overcome the peculiar resistance offered by the surface of the water. What causes that resistance?

SURFACE-TENSION. The force responsible for the floating of the needle is called 'surface-tension.' It is a man-

FIG. 2

ifestation of cohesion, which is the attraction that binds molecules of like kind to each other. Each molecule within the interior of the liquid is imagined as surrounded by molecules like itself to which it is attracted and which it attracts equally in every direction, whereas the molecules at the free surface of the liquid are attracted only by those internal to themselves, the result being to constrict the free surface of the liquid. In consequence, the surface acts as if it were a stretched membrane or an elastic film. These molecular conditions may be represented graphically. See Fig. 1. The attractive forces acting on a molecule (A) in the body of the liquid may be represented by four resultant axial components, which are equal, so that the molecule is perfectly free to move,

\*This is an attempt to re-state the fundamental principles of flotation. The author will welcome corrections or criticisms.

<sup>1</sup>New needles are slightly greasy, as I ascertained by means of the camphor test, described later. The grease protects the needles from rusting.

<sup>2</sup>I tried five large greased needles, all of which floated; then I tried the same needles after they had been washed in the soda solution and wiped dry on a clean cloth. One time all five sank; the other time four sank.

except for viscous resistance. At the surface itself the upward component disappears and the pull downward on the molecule (B) is uncompensated, any extension of the surface being opposed by a force the horizontal component of which is 'surface-tension'.

This can be illustrated in another way. Each particle of water is attracted by all the particles that lie within its range, which is definitely small, about 0.00000015 cm., therefore the scope of molecular attraction may be considered as a sphere of influence. Thus A in Fig. 2 is attracted, and attracts, within a definite sphere, while B, which is close to the surface, is more attracted inward than outward, since a part of its sphere of attraction lies outside the water.

Such a hypothesis is largely an abstraction; a concrete idea of the nature of surface-tension can be obtained by noting some of its various manifestations.

1. The drawing, or 'soaking up', of water by a sponge.
2. The penetration of wood by varnish.
3. The rising of oil in a lamp-wick.
4. The clinging of ink to a pen.
5. The running of the ink from the pen to the paper.
6. The absorption of the excess of ink by blotting-paper.
7. The cohesion between two plates that have been wetted.
8. Dip a camel's hair brush in water, remove it from the water, and observe how the hairs cling together. Immerse the brush in the water and note how the hairs separate.

9. Watch the water-spiders running over a pool, like boys skating on thin ice. H. H. Dixon actually measured the pressure exerted by the spider's feet on the water. He photographed the shadow of the dimple, then mounted one of the spider's feet on a delicate balance, and made it press on the water until it made a dimple of the same depth as that previously recorded.

10. Pour colored water in a thin layer over the bottom of a white dish; then touch a part of its surface with a glass rod that has been dipped in alcohol. The colored water shrinks from the part touched, leaving an irregular patch of white bottom dry. This is due to the tension of the pure water being greater than that of the alcoholized water, so that the liquid is pulled away from the place where the tension is weak to the place where it is strong.<sup>3</sup> The lively movements of the particles of dye in the water indicate the conflict between the forces of diffusion and surface-tension.

11. The formation of a drop at the end of a tube or from the small mouth of a bottle is another example of surface-tension. Note how the drop grows slowly until it has attained a definite size, and then breaks away suddenly. The size of the drop is always the same for the same liquid coming through the same orifice. It hangs as if suspended in an elastic bag that ruptures when the weight becomes excessive. The contractile character of

surface-tension is manifested in the formation of the drop, the force tending to draw the fragment of liquid into the most compact form, that presenting the least surface in relation to volume, namely, a sphere.

Similarly, if we admit air through a glass tube of given size into various liquids, we shall obtain the biggest bubble in the liquid with the highest surface-tension. If various liquids in succession are allowed to run out of an opening of given size, the largest drop will be that of the liquid having the highest surface-tension.

12. When an iron ring is dipped into a solution of soap

FIG. 3

and then taken out, it will be seen that a film of solution stretches across the ring, covering the whole interior circular space. If a small loop of cotton, previously moistened in the soapy solution, is placed on the film stretched across the circle of the ring, this loop can be made to

FIG. 4

assume, and to retain, any form, such as is shown at A in Fig. 3. If, however, this film within the loop is broken, the loop immediately assumes the form of a perfect circle, as shown at B; and if it is now deformed in any way, it springs back at once to a circle as soon as it is released. Evidently the surface of the solution assumes the shape covering the smallest area. The surface-tension of the liquid acts equally on both sides of the cotton so long as it is wholly immersed, but when the film of liquid inside the loop is broken, the tension acts on one side only—on the open side, where it is in contact with air—and hence draws the loop into a circle, which involves the minimum of extension.

13. The contractile force of surface-tension is shown

<sup>3</sup>This simple experiment is a fascinating exhibition of surface-tension and it should be made by every student of flotation.

in a simple way by blowing a soap-bubble on the large end of a pipe and then holding the other end of the pipe to a candle, whereupon the air escaping from the shrinking bag of the bubble will extinguish the flame, as in Fig. 4.<sup>4</sup>

14. When water is sprinkled on a dusty floor, the dust prevents the wetting of the floor by obstructing the coalescence of the drops, that is, the spreading of the water over the floor. The water draws itself into rolling spherules that become armored by particles of dust. They are nearly round, the larger ones showing a flattening, because the gravitational stress overcomes the contractibility or sphericity of the film. This flattening is shown by a drop of mercury on glass or by the beads of gold on an assayer's cupel.

15. The globular form assumed by water when spilled on a hot stove is another manifestation of these forces. The water is protected from the hot iron by a film of steam, which, as it is formed, decreases the size of the globule until it disappears. If the iron is not sufficiently hot, it becomes cooler and therefore wetted, by spreading of the water, which is instantly converted into steam.

16. Some of the physics of flotation can be illustrated at the dinner-table.

A. Fill a tumbler little over full of water and note the convex surface, indicating the play of a force that prevents the liquid from spilling. It is a contractile force.

B. Fill a wine-glass half-full with port and observe how the wine climbs up the side of the glass, forming a meniscus around the circumference of the surface. This liquid consists of alcohol and water, both of which evaporate, the alcohol faster than the water, so that the surficial layer becomes watery. In the middle of the glass the surficial layer recovers its strength by diffusion from below, but the film adhering to the glass, being more exposed to the air, loses its alcohol by evaporation more quickly and therefore acquires a surface-tension higher than that of the undiluted wine. It creeps up the side of the glass dragging the strong wine after it, and this continues until the quantity of fluid pulled upward collects into drops—called the 'tears of wine'—that run back into the glass.

C. Fill a glass two-thirds full from a 'siphon' containing water that is effervescent because it contains gas in solution. Take three or four small grapes, preferably of the Californian seedless variety. The grapes will sink to the bottom of the glass, but soon they become restless and rise to the surface, one after the other. They do not remain there long; first one and then the other sinks. They will continue the performance for half an hour, hobbling up and down; their activities slowly diminish, and eventually they are left inert at the bottom of the glass. What happens is simple enough. The siphon has come from the refrigerator; the warmth of the room and the lowering of pressure release the carbonic-acid gas, which, in the form of minute bubbles, attaches itself to the grapes, buoying them to the surface as mineral particles are raised to the surface of a pulp in the Potter

process. There the bubbles burst, causing the grapes to fall back. If a couple of grapes collide, the bubbles become detached, dropping their freight, and themselves rising to the surface. At first the grapes rise rapidly and rebound from the surface of the water as if it were an elastic membrane. This is a remarkable effect and should be noted carefully. After the evolution of gas has diminished the bubbles become too few to buoy the grapes, and the performance ends.

Surface-tension is identified with 'capillarity', because it is so marked in a tube the bore of which is only large enough to admit a *capillus*, or hair. When the lower end of a wide tube is held in water, the water inside rises to about the same level as that outside the tube, in accordance with the law of hydrostatic pressure; but when the lower end of a glass tube of small bore, say, 1 mm., open at both ends, is inserted into water, the water rises within the tube and stands at a level higher than the water outside. If, again, the tube be held vertically with its lower end immersed in mercury, the liquid metal inside the tube sinks to a level below that of the mercury outside. See Fig. 5. This is explained by saying that the molecu-

lar attraction of water to glass is greater than that of water to water; whereas the attraction of mercury to glass is less than that of mercury to mercury. The forces of cohesion in a substance and of adhesion between various substances have been measured. Quinke and others have ascertained by experiment that the effect is sensible within a range of one thousandth and one twenty-thousandth of a millimetre. Such is the scope of molecular attraction. The liquid rises in a capillary tube until the weight of the vertical column between the free surface and the level of the liquid in the tube balances the resultant of the surface-tension.

The surface-tension of liquids can be modified. It is decreased by a rise of temperature. For example, place two matches an inch apart on the surface of pure water in a bowl and then touch the water between them with a hot wire. They draw apart promptly, because the surface-tension of the water between them has been lowered relatively to that of the rest of the liquid in the bowl, so that the pull of the water-surface under normal tension is stronger than that of the surface of the warm water between the matches.

The addition of an impurity or contaminant will lower the surface-tension of water. We have seen how this effect is caused both by alcohol and soap. Distilled water has a maximum surface-tension, which is lowered by

<sup>4</sup>C. V. Boys in 'Soap Bubbles'.

almost any substance that is soluble or miscible in it. The soluble substance, or solute, modifies the tension directly, whereas the minutely divisible substance, forming an emulsion, creates a great number of interfaces, or surfaces of contact, each having a lower tension. The particular contaminant, or modifying agent, associated with the early history of flotation was oil, which is partly soluble and readily dispersible. The oil generally used at first was a heavy oil, like oleic acid.<sup>5</sup> By the addition of sufficient oil the surface-tension of water is lowered from 73 to 14 dynes per linear centimetre. The following experiment illustrates this fact. If a wooden match be laid on the surface of tap-water in a pan, so that it remains at rest, and if then a drop of olive-oil be placed on the surface of the water near the match, the match will draw away smartly, because the oil has reduced the tension of part of the water-surface and caused the uncontaminated water to pull away. This modification of the surface-tension of water by a contaminant is one of the fundamental factors in flotation, as we shall see.

Let us now go back to the floating needle. If it is greased, does the grease lower the surface-tension of the water? That can be ascertained by a pretty experiment. If camphor is whittled with a knife above a bowl of water the shavings, dropping on the water, will dance on the surface in a life-like manner suggesting insects in a fit. This phenomenon, as shown by Marangoni, is due to the dissolving of the camphor—a crystalline vegetal distillate—preferably at the pointed end, where the largest area per unit of volume is presented for solution. The dissolving of the camphor lowers the surface-tension of the water in contact and thereby causes the uncontaminated water, with its stronger tension, to pull away from the spot affected by the camphor—as in the colored water and alcohol experiment, No. 10. This causes the chips of camphor to turn and move spasmodically. In order to incite such activity the surface-tension of the water must be greater than that of the camphor solution. As soon as enough camphor has dissolved to modify the whole surface of the water in the bowl or cup, the chips become inert. Likewise if the surface-tension be lowered by the addition of grease the camphor remains quiet. For example, if, while the chips of camphor are lively, the water be touched by a greasy finger—all fingers are slightly greasy—the camphor is quieted immediately. No ordinary 'clean' cooking-utensil is sufficiently free from grease to allow an exhibition of the camphor dance.

Here we have a simple means of detecting the presence of grease or oil in the water upon which the needle is floating. I introduced some camphor chips into the water on which the ungreased needle was floating and they became lively. Then I repeated the experiment with a needle that was slightly greased, by rubbing it with the fingers that had touched my hair, and the camphor appeared unaffected thereby; it was lively. Finally, I smeared the needle with olive-oil; an iridescence on the

surface of the water indicated diffusion of the oil. This time the chips of camphor fell dead as a door-nail and remained wholly inert on the water. Apparently, therefore, the needle will hold to itself a limited proportion of oil, which adheres so selectively as not to contaminate the water; but an excess of oil, more than the needle can hold, will be set free at once to modify the water and lower its surface-tension.

This is a classic experiment, as I ascertained afterward. Raleigh showed that the decrease of surface-tension begins as soon as the quantity of oil is about half that required to stop the camphor movements, and he suggested that this stage may synchronize with a complete coating of the surface with a single layer of molecules.<sup>6</sup>

A reference has been made already to the measuring of surface-tension. It can be done in several ways. For example, a framework, such as is shown in Fig. 6, is constructed out of a transverse bar *AB* and two grooved slips *CD* and *EF*, so as to allow a piece of wire *GHIJ* to slip freely up and down. The wire *HI* is pushed against *AB* and some of the liquid is applied between them. The little pan *X* is loaded with sand so that the wire *HI* is pulled gently from *AB*. The minimum force required to do this is *mg*, the weight of *M* grammes. This weight suspended on the film of liquid between *AB* and *HI* equals the tension of the film on the wire. If the film stretches until the wire *HI* is at *p*, then the film has an area *CE*, *CP*. The total weight *mg* is distributed over the breadth *CE*, whence if *T* represents the surficial tension across the unit of length *CE*, then

$$mg = T \cdot CE, \text{ or } T = \frac{mg}{CE}$$

Another simple way of measuring surface-tension is to make a wire-frame of which one side is movable; thus (Fig. 7) let *ABC* represent a bent wire and *DE* a straight piece. If a film of liquid is spread over the space *DBE* then the surface-tension acting on *DE* will support not only the weight of the wire *DE* but also a small weight *X*. If *W* be the mass of the cross-wire *DE* and its attached weight, then the surface-tension of the film supports *W* and exerts a force *Wg*. The surface-tension acts all along that part (*l*) of the wire *DE* that lies in contact with the film, and it acts at right angles to *DE*. Since the film has two surfaces, if the force exerted on a unit length of *DE* and on one side of the film be *T*, then the upward force on *DE* due to surface-tension is *2Tl*. Hence<sup>8</sup> if there is equilibrium  $2Tl = Wg$ , or  $T = \frac{Wg}{2l}$

This method was suggested by Clerk Maxwell. An ingenious mechanical model for illustrating the definition of surface-tension has been devised by Frank B. Kenrick, of the University of Toronto. He gives the definition as "the maximum quantity of work that can be gained when a surface is decreased in area by one square centimetre", and describes his device as follows: "A pro-

<sup>5</sup>No wonder the judges were puzzled by the technical terms used in flotation lawsuits. 'Oleic acid' is called an oil, whereas 'oil of vitriol' is an acid.

<sup>6</sup>The Encyclopædia Britannica. 11th Edition. Page 267.

jection cell 40 mm. by 10 mm. and 60 mm. high, the upper edges of which have been coated with a film of paraffine-wax, is filled almost to overflowing with water. On the surface is floated a thin shaving of cork 30 mm. by 5 mm. by 1 mm., to which is attached a fine cotton

FIG. 6

thread about 40 mm. long terminating in a little glass hook. The thread passes over a small pulley made from a pill-box and a pin resting in a double Y-shaped glass bearing. Three weights of glass or bent wire weighing

FIG. 7

about 0.1 gramme, 0.07 gm., and 0.04 gm. may be hung on the hook. The middle weight approximately balances the surface-tension, while the lighter one on being pulled down with a pair of tweezers is lifted again by the surface-tension. A fall of 1 cc. produces one square centimetre of surface, namely, 0.5 cm<sup>2</sup> on the forward under side of the cork that is wet with water and 0.5 cm<sup>2</sup> on the upper surface of the liquid in the cell.<sup>9</sup> For the accompanying sketch (Fig. 8) I am indebted to Professor Kenrick, who sent it to me on request. The wax-

ing of the upper edge of the glass cell allows the water, which does not wet paraffine, to rise slightly higher than the level of the glass without overflowing.

By such experiments the force of surface-tension between water and air has been determined to be 3.14 grammes per linear inch or 72.62 dynes per centimetre at 20°C.<sup>10</sup> Many disturbing factors enter into the meas-

FIG. 8

urement of this force, so that divers figures, ranging from 70.6 to 81 have been announced at various times.<sup>11</sup>

This force may seem small, yet the actual tensile strength per unit-area of cross-section of the film is about one-fourth that of the iron or mild steel used in the shells of steam-boilers, although its density is not much more than one-eighth as great as that of the iron.<sup>12</sup>

The surface-tension of a liquid must be stated with reference to the fluid—gas or liquid—in contact, for it is modified by the nature of the substance on either side of the interface. An interfacial tension exists at any surface separating two substances and it has a particular value for each pair of substances. For example, the tension separating mercury from water is 418 dynes per centimetre whereas that separating olive-oil from air is only 36.9 dynes. A drop of water will not spread over

FIG. 9

the surface of mercury but oil will spread over water. The balance of forces is different in the two cases. When a globule of oil is placed on water, the tension of the water-

<sup>10</sup>Theodore W. Richards and Leslie B. Coombs. 'The Surface-Tension of Water, Alcohols, etc.' Jour. Amer. Chem. Soc., July 1915. One dyne is equal to 1.02 milligrammes.

<sup>11</sup>T. J. Hoover in his valuable book 'Concentrating Ores by Flotation' quotes from Clerk Maxwell's article on 'Capillarity' in the Encyclopædia Britannica and gives the figure as 81, but he makes the mistake of saying that it is 81 dynes "per square centimetre." It is a tension, not a pressure.

<sup>12</sup>M. M. Garver. Jour. Phys. Chem., Vol. XVI, page 243.

<sup>9</sup>Jour. of Phys. Chem., Vol. XVI, page 513.

air surface exerts a pull of 73 dynes as against the joint pull (37 plus 14) of the air-oil and oil-water surfaces. Thus  $14 + 37 < 73$ . (Fig. 9) The oil spreads. If soap, in the form of  $\frac{1}{4}\%$  sodium oleate, be added to the water its surface-tension will be lowered to 26 and the oil-water tension will also be decreased, how much I do not know, but certainly decreased, say, to 12; therefore  $37 + 12 > 26$ , and the oil will not spread over the water. On the other hand, the tension of the mercury-air surface has been given as 436 dynes and that of the mercury-water surface as 418. If this be so, then a drop of water will not spread, because  $418 + 73 > 456$ . But Quincke showed long ago that pure water will spread on pure mercury, although the presence of an impurity, such as a slight greasiness, on the surface of the mercury will prevent spreading. According to later determinations of the interfacial tensions, by Freundlich, that of mercury-air is 445 dynes and that of mercury-water 370, so that  $73 + 370 < 445$ , and the pure water ought to spread on the pure mercury, as Quincke stated. If the water be contaminated, so as to lower its surface-tension, it will spread readily even on ordinary mercury, which is not chemically pure and on which pure water will not spread.

**WETTING.** A steel needle floats on water, but a glass rod of the same size sinks immediately; yet the specific gravity of steel is to that of glass as 8 to 2.75. The surface of the water resists rupture by the steel but it is readily broken by the glass; in other words, the glass is readily 'wetted,' while the steel is not. Again, if the glass rod be greased it will float; it ceases to be easily wetted. Here we face one of the underlying phenomena of flotation. The understanding of what constitutes 'wetting' is essential to the subject.

If a drop of pure water be placed on a clean piece of glass, it will flatten itself out so as to increase the space it first touched. If a similar drop of water be placed on a cabbage-leaf, it will not spread, but will retain its spherical form. We say that water 'wets' a glassy surface and does not 'wet' a waxy vegetal surface. A drop of mercury spreads eagerly over gold, but does not spread on glass; mercury wets gold but not glass. The statement is not absolute; it is a question of degree.

If I press the surface of water with a piece of glass the water rises to meet the glass, forming a mound, whereas if I make the same test with a piece of steel the water shrinks away from it, forming a depression. The tendency is for the water to lap the glass but to avoid the steel; the one substance is easily 'wetted,' the other not. The glass and the steel typify the gangue and the sulphide respectively in an ore treated by flotation. If we look carefully at the steel and glass, at the instant of touching the water, we see the conditions sketched in Fig. 10.

Note how ink from a pen will not run on paper that is at all greasy. The paper refuses to be wetted where it is greased. That is why new pens are refractory: the steel has been greased to prevent rusting, like the needles. I used to burn the point of a new pen by aid of a match

in order to cause it to deliver the ink to the paper comfortably. That burned the grease, but spoiled the temper of the pen-point.

The free surface of a liquid is horizontal, but at the contact with a solid the surface is curved, the direction and amount of curvature varying as between different liquids and solids. The water curves upward against glass, whereas it curves downward against steel; it tends to drown the one, but to float the other until gravity

Fig. 10

overmasters surface-tension. The way in which a liquid impinges on a solid is called the 'angle of contact.' For example, in Fig. 11 water is shown in contact with glass. Consider the conditions at the point *O*. The gravitational pull on a minute quantity of the water is negligible in comparison with its own cohesive force; so we can disregard the effect of gravity. The force of adhesion exerted by the surface of the glass is represented by *OA*, the force of cohesion in the water is represented by *OB*, and the resultant of these two forces is *OC*. If the adhesive force of the liquid to the solid exceeds the cohesive force of the liquid, the resultant will lie to the left of the vertical, *ED*, that is, within the solid; and

FIG. 11

FIG. 12

since the surface of a liquid assumes a position at right angles to this resultant force, the water rises on the face of the glass. If, on the other hand, as in Fig. 12, where steel is shown in water, the cohesion of the liquid is greater than the adhesion of the liquid to the solid, then the resultant force lies to the right of the vertical, or within the liquid, which accordingly is depressed at the face of the solid.

In Fig. 11 and 12 the contact-angle is *DOB*. Since the surface of the liquid always assumes a position at right angles to the resultant force, the water will tend to rise on the glass and to sink on the steel. This angle of contact between a liquid surface and a solid is usually the same for the same pair of substances, but there is a subtle variation, which is called 'hysteresis' and it is said to play an important part in flotation. The variation is

connected with the ability of a solid to condense a film of gas upon its surface. This gas-condensing power, or adsorption, can be modified, by acidulation, for example. Sulman has stated that "whereas the angular hysteresis of silica in plain water may exceed  $30^\circ$ , thus indicating that substance to have a definite power to occlude gas and to float, it drops from  $4^\circ$  to nil in water acidulated with sulphuric acid. Galena, on the other hand, retains its full measure of angular variation, or is but slightly affected."<sup>13</sup> This effect of the surface-energy of solids is apparently an important factor in flotation, and it is a pity that the exigencies of patent litigation have prevented Mr. Sulman from contributing more to the technology of the subject.

The angle of contact between water and glass is so acute as to be more nearly zero the purer the water and the cleaner the glass; between turpentine and glass it is  $17^\circ$ ; between mercury and glass it is  $148^\circ$ . In a general way, subject to the variation already noted, the size of the contact-angle measures the capacity for 'wetting.' This angle can be changed by modifying the surface-tension of the water by means of a contaminant, such as oil, or the angle can be altered by modifying the surface of the solid, also by oiling. The oiling of the steel needle increased the angle of contact with the water so that it did not impinge as directly on the needle, and it did the same to the glass rod, but the effect was relatively less on the steel than on the glass because of the higher specific gravity of the former. The force tending to prevent sinking depends upon the radius of the needle, its density relative to that of the water, the surface-tension of the water, and the cosine of the contact-angle.<sup>14</sup> In metallurgical practice the pull of gravity is decisive in so far as it limits the size of particle that can be floated in water. If our needle is too large, it sinks, no matter how favorable the other conditions may be. So the flotation of a particle of mineral is conditioned on the size to which it has been reduced by crushing in the mill. The oiling of the needle increased the upward component of the surface-tension by enlarging the angle of contact, but the use of an excess of oil, that is, more than the needle could hold of itself, served to lower the surface-tension of the water and therefore to diminish the resultant force operating against wetting and in favor of flotation. Thus the oil used in flotation has two possible functions, and they may interfere with each other.

If to the water in which a needle is floating I add a drop of pine-oil, the needle sinks at once because the lowering of the surface-tension enables the water to wet the needle, that is, to diminish the angle of contact so that the water envelops the steel. Let us make some other simple experiments. Take a piece of chalcocite that presents a smooth surface. A drop of water will not spread over it as it will on glass; the globule of water flattens itself on the glass but tends to retain its spher-

ical form on the chalcocite. The glass may typify quartz or some other gangue-mineral. A drop of flotation-oil, such as coal-tar creosote, flattens on the chalcocite, whereas water maintains its sphericity. Coal-tar spreads less on glass than on water, but water spreads more on glass than on chalcocite. Thus water wets mineral less easily than gangue, whereas oil coats mineral more readily than gangue. So we say that gangue has a greater affinity for water than mineral, which, on the contrary, has a greater affinity for oil.

Water drips off oiled copper more quickly than off the unoled; there is more adhesion between the water and the unoled metal; the oil prevents wetting by the water. The effect of the density of the surrounding medium is shown by placing a piece of glass under water, dropping a globule of coal-tar upon the glass, and then raising it out of the water. The globule of oil spreads when lifted out of the denser medium and shrinks when returned to the water, although not quite to its first shape, on account of the adhesive surface. The oil on the galena replaces the water on its surface, but the oil on the quartz is unable to prevent the water from pushing itself underneath and over the surface of the quartz. Thus we have "an instance of the selective action of oil on a metallic sulphide in the presence of water, and the selective action of water on a gangue-mineral in the presence of oil."<sup>15</sup> On this phenomenon largely depends the process for separating valuable mineral from worthless gangue by flotation.

If a piece of galena and a piece of quartz are placed under water on the bottom of a beaker and if a few drops of oil, such as wood-creosote, are dropped upon the water, they will descend through the water owing "to their momentum and the releasing of the surface tension of the water"<sup>17</sup> until one may fall on the galena, on which the oil will spread, while another falls on the quartz, on which it tends to draw into globular form, instead of spreading. Flotation is essentially a selective process. If I throw powdered ore on water, the particles of gangue sink and the particles of mineral float, in accord with our expectation, based on the foregoing experiments and the deductions therefrom, but some of the small particles of gangue will float and some of the larger particles of mineral will sink, because the play of forces is so complex that any single one of them is not uniformly decisive. Flotation is preferential, not absolute.

(To be continued)

FLotation depends upon the presence of substances that will lower the surface-tension of water and are adsorbed by the mineral particles that it is desired to float.

SULPHURIC ACID and other electrolytes increase the surface-tension of water, but this increase is negligible unless acid is added in strong proportions.

# Methods of Driving Pine Mountain Tunnel

By H. DEVEREUX

The Pine Mountain tunnel is being driven in Marin county, California, at a point about three miles west of Fairfax. The tunnel is part of the proposed system for the Marin Municipal Water District, connecting the Lagunitas water-shed with the water supply system for the eastern part of Marin county. It is of horse-shoe section, 8 by 8 ft. net, inside the concrete lining. The total length is 8700 ft., of which about 600 ft. near the two portals will have a 12-in. concrete lining, and the remaining 8100 ft., a 6-in. lining. The quantities per lineal foot are as follows: excavation, 3 cu. yd., theoretical amount of concrete in 12-in. lining, 1.2 cu. yd.; concrete in 6-in. lining, 0.6 cu. yd. The actual quantities of concrete will be about 35% greater, on account of overbreakage. The work is being done under the direction of M. M. O'Shaughnessy, consulting engineer for the district, A. R. Baker, engineer for the district, and C. T. Broughton, resident engineer on the work. The contract was awarded early in December 1916 to McLeran & Peterson, of San Francisco, at \$257,400 for the entire work, or \$29.70 per lin. ft. for driving and lining the tunnel. Work was commenced in the middle of December. Hand-drills were used until about February 1, machine-drills since that time. The actual cost of driving has been about the same for both methods, but the machine work is much more rapid. Up to May 15 about 2000 ft. of progress was made on the east end, and 1000 ft. on the west end. Concreting commenced about June 1. The maximum progress in driving for any one month has been 568 ft. in the east heading, or 19 ft. per day. The average progress since the machine drills were installed has been 13 ft. per day in the east end, and 10 ft. in the west end.

It will prove of interest to compare records of other American tunnels having nearly equal sections. On the Sheep Creek tunnel in greenstone and slate the maximum progress was 661 ft. per month and the average for a period of six months, 596 ft. per month. At the Alaska-Gastineau mine, an 8 by 10-ft. tunnel was driven 8800 ft. at a rate of 544 ft. per month. The maximum monthly progress in the Roosevelt tunnel, which had a 6 by 10-ft. section and was driven in Pikes Peak granite, was 435 ft., and the average was 292 ft. The Elizabeth Lake tunnel on the Los Angeles Aqueduct was driven 604 ft. in one month through black shale. The section was 12 by 13 ft. The Red Rock tunnel, also on the Aqueduct was driven 1061 ft. in one month through cemented sandstone. An 8 by 8-ft. tunnel for the Arizona Copper Co. was driven 799 ft. in

one month through porphyry. The average monthly progress was 669 ft. The Gunnison tunnel, 6 by 10½ ft., was driven 824 ft. in one month through soft limestone. The Mt. Royal tunnel, 8 by 12 ft., was driven 810 ft. in one month through limestone. An 8½ by 9½ ft. tunnel at Mammoth, California, was driven 395 ft. in one month. The average progress was 316 ft. The

EAST PORTAL OF TUNNEL

Laramie-Poudre tunnel, 7½ by 9½ ft., was driven 653 ft. in one month through granite. The average was 525 feet.

The power-plant for the Pine Mountain tunnel is on the Bolinas road about three miles west of Fairfax. The east portal is about 1000 ft. from the power-house. The west portal is nearly two miles southwest from the power-plant. Until recently the west portal could be reached only by pack-train, but the trail has recently been improved so that light loads can be hauled over the mountain.

The compressor-plant consists of three 25-hp. Fairbanks-Morse Y-type semi-diesel engines, and three 8 by 8-in. Sullivan compressors. The pressure maintained at the compressor is 100 lb. per sq. in. A study of records on 25 other long tunnels shows that this is the average pressure maintained. The lowest was 85 lb., on the Strawberry tunnel, and the highest, 120 lb. on the Laramie-Poudre. Six tunnels used 100 pounds.

Angeles Aqueduct recommends a 25-lb. rail where concrete is to be hauled. Where heavy cars are used, a mechanical dumping-system is required.

Considerable trouble has been experienced at the west end of the Pine Mountain tunnel on account of water. There are 'pockets' of water that give a large flow for a few days and then run dry, making pumping a difficult matter. This has been remedied by cutting a ditch to drain the water back from the face of the tunnel. This matter of drainage is frequently a considerable item of expense in long tunnels. The cost of pumping at the Mile Rock tunnel was \$1.30 per lin. ft. At the east end of the Strawberry tunnel, the wet end, the cost of pump-

WEST PORTAL OF TUNNEL

ing was \$1.36 per lin. ft. At the Roosevelt tunnel a drainage ditch 4 by 6 ft. was excavated at a cost of \$1.10 per ft. If an 8 by 8-in. ditch is carried under the track in the middle of the heading, lined on the sides and covered with a 2-in. plank at an elevation of 18-in. below grade at the same time as the rest of the drilling is done, the water-problem at the lower end of a tunnel will be easily and economically handled. A similar arrangement is advisable at the upper end of the tunnel, whenever the grade is such that the ditch need not be over 4 or 5 ft. deep at the portal.

So far, but little timbering has been required. About 10% of the tunnel has been side and top-lagged, while for about 5%, timber sets in the arch only have been used with the top-segments lagged. In the first 2000 ft. of tunnel 20,000 ft. B.M. of timber has been used, or 10 ft. B.M. per foot of tunnel. The cost of placing timber full-lagged is about \$15 per M.B.M. Where arch-sets and crown-bars are used the cost will be greater, about \$25 per M.B.M. Where timber is cut in the woods

nearly a man can cut and frame 1000 ft. B.M. in 4½ days.

The overbreakage thus far has been small, not exceeding 35% of the net area of the concrete section. On the east end, the ground is being drilled to the full section, on the west end to about 80% of the full section, requiring trimming along the entire length in the latter case. On the Los Angeles Aqueduct some tunnels were driven and trimmed so closely that the excess yardage did not exceed 15 or 20% of the theoretical yardage of concrete, but the cost of trimming amounted to as much as \$2 per lin. ft. of tunnel. The conclusion with regard to hard-rock tunnels was that the excess yardage of concrete lining should not be over 30 to 40%. When a cubic yard of concrete in the net section was required per lin. ft. of tunnel, a 100% excess was valued at \$6 to \$7 and a 30% excess at \$1.80 per lin. ft. It was found to be the best practice to excavate the sub-grade at the start so that the top of ties is at the bottom of the theoretical sub-grade, so as to avoid expensive trimming and delays when the concrete lining is placed. In the Mile Rock tunnel the theoretical quantity of concrete per lin. ft. of tunnel was 1.6 cu. yd., and the actual 2 cu. yd., or a 25% excess.

The cost of driving the Mile Rock tunnel was \$4.75 per cu. yd. or \$27 per lin. ft. of tunnel. The cost of lining was \$9 per cu. yd. of concrete, or \$18 per lin. ft. of tunnel. In general the cost of lining small-section tunnels where compressed air is used to make and place the concrete, and wooden forms are employed, is \$1.60 per lin. ft. for forms and \$1.40 per cu. yd. for labor and royalty in placing concrete, plus the cost of materials, aggregate, and power, and the distributed general expense and liability insurance. On the Mile Rock tunnel the overhead for general expense and insurance was 15% of the total cost to the contractor. On the Pine Mountain tunnel the liability insurance and bond are carried by the water district and do not appear in the contract price.

The following is the scale of wages paid on the Pine Mountain tunnel:

Drillers .....	\$3.75	Dump-men .....	\$3.00
Helpers .....	3.00	Foremen .....	6.00
Shovelers .....	3.25	Compressor-engineers ..	3.50
Teamsters .....	3.00	Pipe-men .....	3.00
Blacksmiths .....	4.00	Packers .....	3.00
Helpers .....	3.00	Common labor .....	2.50

The maximum monthly progress has been 568 ft. or 19 ft. per day. For this rate of progress, which was at the east end, the cost per lin. ft. to the contractor is as follows:

Drilling .....	\$1.67	Teaming .....	\$0.30
Shoveling .....	1.90	Packing .....	0.25
Hauling .....	0.67	Miscellaneous plant, pipe-	
Dumping .....	0.48	line, track .....	2.00
Blacksmith .....	0.37	Heavy plant, engines and	
Pipe-men .....	0.16	compressors .....	1.00
Powder .....	1.80	Drill steel, repairs .....	0.30
Power .....	0.65	Timbering, material ....	0.20
Bonus .....	2.00	Timbering, labor .....	0.12
Constr'n and maint'nce			
roads and trails.....	0.25	Total cost per foot....	\$16.12

A bonus of \$0.25 per man per ft. is paid for each ad-

Air is conveyed through a  $3\frac{1}{2}$ -in. pipe, 1000 ft. to the east portal, and 10,000 ft. to the west portal. Three hundred cubic feet of free air per minute is supplied, which is sufficient to run three drills and also the forges. The loss of pressure at the west end does not exceed 2 lb. Records on nine long tunnels show capacities of plant ranging from 247 to 868 cu. ft. of free air per minute, with an average of 550 pounds.

The D'Arcy-Cox formula for the conveyance of compressed air in pipes is

$$D = \frac{c \sqrt{a^3}}{\sqrt{L}} \times \frac{\sqrt{P_1 - P_2}}{W_1}$$

Where

$D$  = volume of compressed air in cubic feet per minute discharged at final pressure.

$c$  = a coefficient, ranging from 45 for a 1-in. to 60 for a 6-in. pipe.

$d$  = diameter of pipe in inches.

$L$  = length of pipe in feet.

$P_1$  = initial gauge-pressure in pounds per square inch.

$P_2$  = final gauge-pressure in pounds per square inch.

$W_1$  = density of the air or its weight in pounds per cubic foot.

Diameter of pipe, inches	TABLE I		Value of $c\sqrt{d^3}$
1	.....	.....	45
$1\frac{1}{4}$	.....	.....	105
$1\frac{1}{2}$	.....	.....	155
2	.....	.....	300
$2\frac{1}{2}$	.....	.....	530
3	.....	.....	875
$3\frac{1}{2}$	.....	.....	1300
4	.....	.....	1860
5	.....	.....	3300
6	.....	.....	5270

TABLE II

Values of  $\frac{\sqrt{P_1 - P_2}}{W_1}$

Final pressure, lb. per sq. in.	Losses of pressure $P_1 - P_2$ in pounds							
	1	2	3	4	5	6	8	10
70	1.5	2.1	2.6	3.0	3.3	3.6	4.1	4.5
80	1.4	2.0	2.4	2.8	3.1	4.0	3.9	4.3
90	1.3	1.9	2.3	2.7	3.0	3.2	3.7	4.1
100	1.2	1.8	2.2	2.6	2.8	3.1	3.6	3.9

Example: Given a  $3\frac{1}{2}$ -in. pipe, 10,000 ft. long, how many cubic feet of air per minute at an initial pressure of 90 lb. can be transmitted, with a loss of pressure of not more than 2 pounds?

From Table I, opposite a  $3\frac{1}{2}$ -in. pipe, find 1300.

Square root of 10,000 = 100.

$1300/100 = 13$

From Table II, for drop of 2 lb. at 90 lb. final pressure, find 1.9.

$13 \times 1.9 = 23.7$

$90 \text{ lb.} + 14.7 \text{ (atmospheric)} = 104.7$

$\frac{23.7 \times 194.7}{14.7} = 170 \text{ cu. ft. (approx.) of free air per minute.}$

In using Table II, it will be noted that the initial and final pressures are taken as the same. Should greater

STANDARD SECTIONS FOR TUNNEL

refinement be required, interpolate for the difference, remembering, however, that a slight leak in the line may change the results.

Three No. 18 Leyner drills with a  $1\frac{1}{4}$ -in. chuck, 24-in. feed, and six sets of  $1\frac{1}{4}$ -in. hollow steel from 24 to 96 in. long, are used. There is an 18-gal. water-tank and an air-line manifold. The drills are mounted on horizontal bars. Jackhamers are used for trimming. On other long tunnels, preference was about equally divided between vertical columns and horizontal bars.

The duty of a No. 18 Leyner drill in this tunnel is 5 ft. of hole per hour, using 1000 cu. ft. of free air at 100 lb. pressure per lin. ft. of hole drilled. The cost of

drilling, including bonus is \$0.20 per ft. This estimate allows for delays.

The cost of fuel and lubricating oil for a 135-day run was as follows: 11,000 gal. fuel-oil, 24 Baumé gravity, at \$0.032 per gallon = \$352; 250 gal. valvoline, strained and used twice, at \$1.35 = \$324; hauling, three miles from railroad, at \$0.005 per gallon, = \$55; total, \$731.

The plant was run continuously and 62½ hp. was developed. This gives a cost of 0.36c. per hp. hour for fuel and lubricating-oil. This amount of power is sufficient for three drills and two forges. The cost of labor at the power-house is \$320 per month. During March the total progress in both headings was 854 ft., and the cost for power was \$0.65 per ft., \$0.29 for fuel and \$0.36 for labor. A 25-hp. Fairbanks-Morse Y-type engine has just been installed to operate a 220-volt, 25 kilowatt generator, which will be used to run a plant for lighting the tunnel and a rock-crusher for crushing aggregate for the concrete lining.

Purchased electric power on four other long tunnels cost from \$1.65 to \$2.15 per lin. ft. or an average of \$1.90. Electric power generated on the work for the Elizabeth Lake tunnel on the Los Angeles Aqueduct cost \$5.25 per ft., and on the Strawberry tunnel, where it was transmitted a distance of 23 miles, \$5.50 per ft. On another tunnel, where steam was used, with wood for fuel, the cost for power was \$2.50 per ft. Where steam was

time that should be allowed for delays after blasting, requires a capacity of 4000 cu. ft. of air per minute. For respiration allow 75 cu. ft. per man per minute, and 150 cu. ft. per animal. The average rated capacity of ventilating apparatus used on 16 long tunnels was 3400 cu. ft. per minute. The size of the ventilating-pipe ranged from 10 in. for the Carter and Mission tunnels, to 18 in. for the Elizabeth Lake and 19 in. for the Central tunnel. Where light-gauge sheet-metal pipes are used for ventilation, it is advisable to build a small bulkhead of track-ties in front of the pipe before blasting in order to prevent collapse of the pipe.

Table III gives the diameter of pipe in inches required to deliver 4000 cu. ft. of free air per minute for lengths of pipe from 1000 to 14,000 ft., and for pressures from 1 to 6 pounds.

TABLE III

Length of pipe, ft.	Pressure, lb.				
	1	2	3	4	6
1,000 .....	12	10	..	..	..
2,000 .....	14	12	11	10	..
3,000 .....	15	13	12	11	10
4,000 .....	16	14	13	12	11
5,000 .....	17	15	13½	12½	11½
6,000 .....	..	15½	14	13	12

12,000 .....	..	..	16	15	13½
14,000 .....	..	..	..	..	14

INTERIOR OF COMPRESSOR PLANT

used with crude-oil for fuel, the cost was \$2.28 for fuel, and \$0.80 for labor.

For ventilation, 1000 ft. of 10-in. pipe has been laid at each heading, reducing to 8-in. for the remainder of the distance. This pipe has been found to be too small, and is to be replaced with a 12-in. pipe, using a blower working at a pressure of 4.5 lb. per sq. in. To clear a tunnel of foul air in 15 minutes, which is the maximum

For illumination, acetylene lamps on the men's caps and candles have been used, but as already noted, an electric-lighting plant has now been installed. Acetylene lamps have been used on several long tunnels, small lamps being used on the men's caps and larger stationary lights being placed 150 ft. apart along the tunnel. This is an economical method of lighting. Electric lights are usually employed where electric hauling is done. The cost of lighting the Mile Rock tunnel with electricity was \$0.50 per ft. of tunnel. In wet tunnels, electric lights are uncertain.

The rock penetrated so far in the east end of the tunnel is sedimentary with intrusive igneous rock. On the west end there is Franciscan sandstone, black serpentine, and hard boulders, with some diabase. The rock at the west end is harder than at the east end. The number of holes per round at the east end is 9 to 14, and 14 to 16 at the west end. Six feet of hole is drilled per round, the wedge-cut system of arrangement being used. Forty per cent L. F. gelatine powder is used, supplied by the Hercules Powder Co. In the east end, 9 lb. of powder, 19 ft. of fuse, and 4 caps are used per lin. ft. of progress. In the west end, 15 lb. of powder, 26 ft. of fuse and 4 caps are required.

Records of other long tunnels show that the wedge-cut was used in 19 instances, the pyramid-cut in 4, and the bottom cut in 7. An analysis of the depth of holes generally used in American practice, would lead one to infer that the most successful driving was secured when the average depth of the holes was from 60 to 80% of the

hole to 5 or 6 sq. ft. of face of heading, and in igneous formations, one hole to 2.5 to 4 sq. ft. of face.

The amount of explosive used in small tunnels ranges from 3.5 to 10 lb. per cu. yd. of material removed. Bottom-cut holes appear to require more powder than pyramid or wedge-cut holes. As regards percentage of gelatine powder used, practice has ranged from 40% in six tunnels to 100% in the Roosevelt tunnel, which was driven through Pike's Peak granite. Loading the bottom of the hole with 80 to 100% powder and the rest with 40 to 60% has given good results in a number of cases. On the Grapevine division of the Los Angeles Aqueduct 40 and 60% ammonia powder was used. There was comparatively little difference in the effect of the two grades. Ammonia powders are affected by moisture and are not suited to wet tunnels. The gases from the ammonia are disliked by the workmen.

It is best to place the cap near the top of the charge and tamped with powder, although many powder-men prefer placing the cap at the bottom of the hole. A cap has recently been placed on the market that acts like a time-fuse, enabling the cut-holes, relievers, back-holes, and lifters to be fired at intervals and in rotation by an electric battery.

On the east end there are two drillers and one helper per shift, and one driller and one helper per shift on the west end. Three shifts are worked and as many as five rounds or 30 ft. of progress has been made in 24 hours, requiring 150 ft. of drill-hole per drill for each 24 hours. Four shovelers are employed on a shift in each end, two working at any one time and two resting. They handle from 10 to 15 cu. yd. per man per shift. The shovelers use square-pointed shovels, and shovel from steel floor-plates,  $\frac{1}{4}$  in. by 4 by 6 feet.

The material is transported by mules in turn-table end-dump cars of 25 cu. ft. capacity. When the work has progressed so far that mules cannot handle the material economically, it is proposed to remodel White or Stanley steam-automobiles to do the hauling. Such remodeled machines are now being used successfully on the Twin Peaks tunnel. At the east end the material is dumped close to the portal. On the west end it has to be hauled for some distance. The track has an 18-in. gauge and is laid with 27 lb.-rails. The original intention was to use 25-lb. rail, but it happened that a quantity of 27-lb. rail was available.

There seems to be no established practice regarding types of cars or track for this class of work. On 7 tunnels, turn-table end-dump cars were used, on 4 common end-dump cars, on 7 side-dump cars, and on 4 rocker-dump cars. On the Los Angeles Aqueduct, rocker-dump cars with a capacity of 32 cu. ft. were used, while on the Catskill Aqueduct side-dump cars with a capacity of 40 cu. ft. were employed. Sizes of cars varied from 1 ton up to 40 cu. ft. The smaller cars are more convenient since in narrow tunnels the empty cars can be made to pass the loaded ones by simply tipping the former off the track. Weights of rails have ranged from 12 to 36 lb., and gauges from 18 to 36 in. The final report of the Los

WEDGE-CUT, PYRAMID-CUT, AND BOTTOM-CUT SYSTEMS  
(From Brunton and Davis, Modern Tunneling)

width of the heading for wedge and pyramid cuts, and 60 to 80% of the height for the bottom cut. In cases where deeper holes had been used, and the depth of holes was later reduced according to the above rule, there was an increase of speed of as much as 20% and a decrease of powder used of as much as 25%. The number of holes per round is dependent upon the character of the rock. An approximate rule for sedimentary formations is one

ditional foot over 14 ft. per day, to all men who remain during the month. The cost at the west end is about the same as at the east end. The rate of progress is less, but on the other hand there is no bonus. Assuming that the excavation runs 3 cu. yd. per lin. ft. of tunnel, the cost per cu. yd. is approximately \$5.40.

Other miscellaneous items are as follows: Cost of camp-buildings, etc., \$25 per man for a 70-man camp. The cost of laying the 3½-in. pipe for the compressed-air line over the mountain was \$0.08 per ft. for distribution, and \$0.04 for laying, a total of \$0.12. The cook-house, caring for 40 men, uses 1 bbl. fuel-oil in 8 days.

## Memoranda on Submarines

The Engineering Committee of the National Research Council issues the following data to guide those desirous of helping to circumvent the Enemy's submarine campaign by means of invention and suggestion. Any communication on the subject should be addressed to W. F. Durand, Vice-Chairman of the Committee, at Washington.

Submarines operate singly or in groups as may seem best suited to local or special conditions.

They are supposed, where circumstances favor, to lie on the bottom at rest and with listening devices attempt to detect the approach of vessels. On receipt of evidence that a vessel is approaching, they rise to a level permitting observation with periscope, and then maneuver accordingly. When in water too deep to permit lying on bottom, the submarine must maintain steerage way in order to hold its level of submergence. The minimum speed at which this can be done will range with circumstances from 2 to 4 knots. The maximum depth of submergence is about 200 ft. The usual depth of running is from 50 to 100 feet.

They have been supposed to return to the home base at intervals of 30 to 35 days. The total radius of action will presumably range from 5000 to 8000 miles at a moderate cruising speed of 10 or 11 knots. The high speed emerged will range from 14 to 18 knots, or possibly more in latest designs. The maximum submerged speed is about 10 knots.

Hidden bases have been presumably used off the Irish and other coasts. There have also been suspicions of bases on the coasts of Greenland and Iceland. Submerged bases for oil and supplies have also been employed.

The time required from emergence to submergence will range from 1 to 3 or 4 minutes, according to circumstances. When submerged near the surface, the time required to raise the periscope, take a quick observation and lower it again, may range from 15 to 30 seconds. If desired, the submarine can follow an undulating path, rising and submerging alternately, at frequent intervals, at will. Or otherwise it may run fully submerged but near the surface and take frequent observation through the periscope. Modern submarines are provided with

two or three periscopes. The loss or destruction of one, therefore, will not necessarily disable the boat.

Torpedoes fired from submarines are presumably aimed by changing the direction of the boat. This, however, is not assured in all cases. The torpedo, in order to run true, must travel at an immersion of about 10 ft. In smooth water it may be run at a shallower depth than in rough water.

Submarines may operate at night with less liability of detection, but with, of course, greater difficulty in picking up their target.

Submarines use the gyroscopic compass.

Sounds produced by the movement of a submarine through the water, including those traceable to the propeller, to movements of the rudder, etc., should permit of detection by the use of modern refined sound detecting devices.

The distance at which a protecting net, plate, or shield or other means of exploding the torpedo before reaching the side of the ship must be located in order that such distance will render the effect of the torpedo harmless, will depend primarily upon (1) Weight of explosive charge, (2) Depth of torpedo when exploded, (3) Strength of the ship's structure. With modern torpedoes and a depth of 10 or 12 ft. and with the structure of modern merchant ships, distances of 20 or 30 ft. would perhaps be required in order to give good assurance against injury. With rough water and possibly much less submergence at the time of explosion, reduced distances of 15 or 20 ft. might prove sufficient. Experimental investigations on this subject show a very wide divergence among the results and no precise rule can be given. It may be added, however, that naval constructors generally are satisfied that the distance at which protecting plates or shields would have to be placed in order to secure immunity is so great as to render their use of very doubtful practicability.

BRITISH export prohibitions indicate the relative importance of many of the minerals and metals in the conduct of war as revealed by the experience of our Allies. The prohibited articles are classified under three heads, in the order of their importance. Class A are the most necessary, and their exportation is absolutely forbidden; class B may be exported to other parts of the British Empire; while class C may be sent to the Allies of Great Britain but not to neutral countries. Under class A are the following: lead compounds; manganese compounds; mercury nitrate; nickel nitrate; sulphur and preparations containing that element; compounds of titanium and zirconium; all articles manufactured wholly or in part of copper; galvanized sheets; iron and iron alloys containing chrome, cobalt, molybdenum, nickel, tungsten, or vanadium; magnesite; magnesium and its alloys; mercury, platinum and alloys of platinum; railway materials; silicon-manganese; special steels containing tungsten, vanadium, or molybdenum; uranium in any form; iron wire; zinc ashes, zinc and its alloys aluminum in any form; and zirconium and its alloys.

## Recent Vulcanism in Salvador

By C. ERB WUENSCH

San Salvador, the capital of El Salvador, the diminutive republic of Central America, is situated in a region of unusual vulcanism. It was the volcano San Salvador, five miles west of the capital, that was responsible for the recent disaster. This volcano has been quiet since its terrible eruption late in the 16th century. In the year 1625, Thomas Sage, the celebrated English traveler, mentions the appearance of a new volcanic vent in the place now occupied by the volcano Izalco, 35 miles west of the capital and 15 miles north-east from the Pacific seaport of Acajutla. It was, however, not until 1770 that this new vent assumed the status of a volcano. It has, until a year ago, been continuously active. Where the volcano now stands was formerly a large level plain, upon which was situated one of the richest and largest cattle estates of the old Spanish days. During this short period of activity it has built its cone from practically sea-level to its present altitude, which, according to Sonnensternst, is 4973 ft. above tide. Ever since its beginning, great columns of smoke, accompanied by frequent irregular eruptions of small magnitude, continually rose from its crater. It was a marvelous spectacle for the passengers on Pacific steamers as they passed the port of Acajutla, especially at night, when the heavens were illuminated periodically with weird red reflections accompanied by deep heavy rumbling sounds. Often the molten lava could be seen pouring out of the crater and running down the slopes of the volcano. Izalco was well named 'the safety valve of Salvador.' During its period of activity no great eruptions have taken place in Salvador, but slight earthquakes were frequently felt and small amounts of smoke were occasionally seen arising from some of the older volcanoes in the Republic.

About eight months ago, shortly after Izalco ceased its activity, the old San Miguel volcano 70 miles east of San Salvador, situated near the city of San Miguel, commenced to emit unusual volumes of smoke from its huge crater. This renewed activity gave the inhabitants considerable fear, but as the appearance of the smoke waned they ceased to be uneasy. In this connection it might be of interest to relate a strange bit of prophesy on the part of a geologic friend of mine in San Francisco. On June 7 I called upon him, and in the course of conversation he inquired particularly about the volcanoes of Salvador. When informed that Izalco had become quiescent he asked "Is there any new volcanic activity?" Upon being told no, he shook his head and said, "That means trouble." The very next morning cablegrams were received telling of the volcanic eruption and earthquake at San Salvador. This eruption took place through its vent on the western side of the volcano, on the side distant from the city. It was because of the position of the vent that the capital was not more severely damaged. Quezaltepeque, a town nine miles north-west of the city of San Salvador, suffered the most damage.

In this region calcareous and argillaceous formations, derived from the weathering of the volcanic tuffs and ashes, predominate. They possess features characteristic of sedimentary rocks for which they might easily be mistaken. In the immediate vicinity of San Salvador volcano is a large granite porphyry intrusion through the basaltic lava of which the cone is composed. In the lava-beds of Izalco is found a mineral salt, chloride of ammonia associated with sulphur. The lava is stained a variety of colors; yellow, green, red, and purple, due to the oxidation of small amounts of various metallic sulphides.

A possible explanation of the transference of the activity from volcano Izalco to that of San Salvador may be found in the sealing up of the vent of Izalco, the molten magma then stopping its way laterally until it made a connection with the older vent in the volcano of San Salvador, which had been occupied by a crater-lake. The heat from the magma coming in contact with the water seepage from the lake generated sufficient steam to shatter the rocks, relieve the pressure of the superincumbent column of rock, and start the eruption.

It might be of interest to recall the unusual volcanic activity that occurred in 1880 in Lake Ilopango, a crater-lake eight miles long and five miles wide and from 500 to 1500 ft. deep, situated six miles east of the capital. The surface of the water is 1200 ft. below the mean level of the surrounding plain. This suggests that here was once a volcano of great size. In that year two volcanic cones rose from the depths of the lake and extended about 200 ft. above the surface, and ejected smoke and ashes. The water subsided 40 ft. and found an outlet into the Jiboa river and flooded the surrounding country. Goodyear estimated that 635,000,000 cubic metres of water was released from the volcano. Other famous volcanoes in Salvador are Santa Ana, with an elevation of 6615 ft., very slightly active at the present time; San Miguel, elevation 6500 ft., also slightly active; and San Vicente, elevation 7793 ft., long extinct. Along the slopes of many of the volcanoes are situated the richest coffee plantations in the country. The volcanic ashes make an exceedingly rich soil. A cablegram received from President Melendez of Salvador stated that the ashes from the present eruption would prove beneficial to the soil and offset some of the damage done by the earthquake.

CO-OPERATION of American and French and English physicists has been sought by the National Research Council in an effort to find means to combat the submarine. A conference for this purpose has been held in Washington, at which Charles Fabry, Henri Abraham, M. le Duc de Guiche, Sir Ernest Rutherford, and Commander Cyprian Bridge were present, along with a number of American physicists. It is hoped to obtain the co-operation of experimenters throughout the country having laboratory facilities at command. It is pointed out that the best laboratory equipment now available for work of this kind is found at the Universities in the United States.

## Mining in Utah

By L. O. HOWARD

Several problems are being faced by local operators. At a time when metal prices stimulate intensified production, numerous strikes have served to interfere seriously with operations. Tintic and Park City have both been handicapped by labor troubles that were ultimately settled through the agency of a member of the new State Industrial Commission. Some annoyance was also caused at the plants of the Utah Copper Co. through small strikes of men engaged not directly in operation but in construction, repair, and maintenance. Finally came the strike at the International smelter that resulted in closing the works. Although the Federal Department of Labor has a representative on the ground, a settlement has not been effected at the time of this writing. The principal point of difference is an increase in wages of 50 cents per day. There has been no violence, but it is to be feared that when the furnaces are again blown-in the scarcity of labor will be felt severely, inasmuch as many of the men have left for other parts.

There is considerable inquiry for lead mines. Bingham, Park City, and Tintic are pushing production to the limit. Transportation in Big Cottonwood is still difficult, and maximum shipments have not yet been attained. The Cardiff has several hundred tons of ore scattered up and down the canyon during the winter, but is adding to its fleet of motor-trucks and expects to clean-up the accumulation soon. The Maxfield, which has been the only other persistent shipper, has been closed pending an investigation of its affairs. A new faction in the directorate has obtained control and has stopped all work. The ore has been coming from points several hundred feet below the adit-level, and incidentally below the level of the creek; therefore the excessive cost of pumping has prevented a profit. While the ore was rich, it occurred in small lenses so irregularly distributed as to cause development to bear an undue share of expense. It is probable that work will be continued on the 1200-ft. or adit-level in an effort to find other ore-shoots above that horizon, similar to those that proved profitable in the earlier history of the mine.

The Kennebec Mining Co., owning property adjoining the Cardiff, proposes to begin development with funds loaned to it *pro rata* by the stockholders, at 8%. This method of financing has been adopted owing to the non-assessable character of the stock. Development in many other properties in the canyon is said to be encouraging, notably on the Big Cottonwood Coalition and the American Consolidated Copper.

Little Cottonwood is active as never before in recent times. In the first three weeks of June the Michigan-Utah Consolidated Mines Co. made settlements on 36 cars of ore, averaging for the most part \$25 per ton. One or two cars netted over \$70 per ton and two cars \$38. The company is able to ship \$20 ore at a profit. It reports the beginning of shipments of copper-silver ore

from the Copper Prince tunnel. The ore is said to be of greater extent than elsewhere in this locality. While the limits of the deposit have not been determined, it has been found that over a width of 30 ft. there is a uniform high iron content and that the copper varies from traces to as high as 20%, and much shipping ore has been blocked out. This development is daily gaining greater importance, and it is distinctly possible that a fair-sized copper deposit is to be opened in the Cottonwoods at last. Many engineers have been confident that excellent copper deposits would be found at the east end of both the Big and Little Cottonwood districts. The Michigan-Utah development tends to confirm this opinion as to Little Cottonwood, and showings recently made in the Big Cottonwood Coalition are likewise favorable.

The Copper Prince tunnel has been connected to the aerial tramway of the Michigan-Utah company. This conveys much Alta ore to Tanner's Flat, about four miles down the canyon, where it is loaded into narrow-gauge cars and dropped down to Wasatch, another four miles, on the tracks of the Little Cottonwood Transportation Co. At Wasatch it is again transferred into cars of the Salt Lake & Alta railroad, a branch of the D. & R. G., which carries it to the smelters at Midvale and Murray. Eighty-five men are now on the company's pay-roll, and it is intended to keep a force of 100 men at work during the year.

During the first quarter the Emma Consolidated shipped 33 cars of ore from Alta that netted nearly \$30 per ton. This company is shipping 60 to 70 tons per day at present, and expects to go on a 100-ton basis soon. There has been some dissatisfaction with the facilities afforded by the Salt Lake & Alta railroad, and some ore is being hauled to the smelters from Wasatch in auto-trucks. The railroad company is preparing to lay heavier rail, after which better service is anticipated. The Alta Consolidated has started the shipment of some rich ore taken out during the winter. The Sells is at the point of shipping and is expected to make a steady output during the shipping season. The South Hecla maintains a regular production.

At Bingham mining is on a larger scale than ever. The Utah Copper Co. is milling 38,000 tons per day. The completion of the leaching-plant has been again delayed by poor deliveries of structural material and is now expected about the first of September. The work is 75% finished. The initial capacity is set at 4000 tons, although it is planned to increase to 10,000 tons per day as soon as possible. There is about 40,000,000 tons of oxidized material that should yield close to 13 lb. copper per ton. A short time ago the County Assessor announced his intention of taxing the tailing-dumps of the company, estimating that there is \$68,000,000 worth of available copper in 57,000,000 tons of tailing, representing 35 to 40% of the original content of the ore, most of which could be recovered by flotation. If this policy of taxation is carried out it will affect many other companies in the State that have treated sulphide ores and accumulated tailing-piles containing recoverable metals.

If the County officials seek to enforce their ruling it will doubtless mean another legal battle. If the tax-gatherer is successful, what is to prevent his applying the same logic to oxidized tailing, or practically any kind of tailing that may contain economic minerals?

Further troubles are imminent in connection with the insurance rate, which the State Industrial Commission is seeking to establish under the provisions of the Workmen's Compensation Act. This act has been declared obligatory on workmen and on employers of more than four men. Some of the premiums per \$100 of pay-roll are: assaying, \$1.68; ore concentration, \$4.04; smelting, \$6.11; metalliferous mines, \$5.59; and coal mines, \$9. These rates are said to have been adopted from figures furnished by the Workmen's Compensation Service Bureau of New York, which, incidentally, is also engaged in an attempt to boost the Colorado rates another 25%. Colorado rates furnish an interesting commentary. They are \$3.85 per \$100 of pay-roll for metalliferous mines and mill operators. These rates enabled the State Insurance Fund to provide for all expenses, losses, compensation, and surplus, besides paying a dividend of 23% of the amount paid in. The local chapter of the American Mining Congress, in collaboration with the mine operators, has been conducting an exhaustive investigation into the matter and is making an earnest attempt to obtain a fair rate. The casualty expert engaged by these interests has recommended that the rates for metalliferous mines be reduced to \$4.25, coal mines to \$6.04, and that mill-rates be also reduced.

Reports of last month's ore shipments show that Tintic mines shipped 889 cars, bringing the total for five months to 4337 cars, and that Park City mines produced 8447 tons. The Judge Mining & Smelting Co. held second place with 2376 tons, leading the Silver King Consolidated, which reported 1595 tons, and trailing the Silver King Coalition, which shipped 2506 tons. It is expected that the large increase in shipments by the Judge company in June will place it at the head of the list. The Tintic 'car' seems to be as precise a measure as the Joplin 'can.' No close estimate of tonnage is possible from Tintic reports.

Among the Bingham mines, Ohio Copper reports a monthly profit of \$70,000. A break in a reservoir on the Price river has resulted in the destruction of several miles of the main line of the Denver & Rio Grande track, and has completely isolated the Carbon County coal mines, aggravating the usual coal shortage in Utah. Several thousand men are thrown out of work. All through service on the railroad between Denver and Salt Lake City has been suspended. Several steel bridges went out and it is estimated that temporary repairs cannot be made in less than two weeks. According to later news the wash-out on the Denver & Rio Grande railroad will cause suspension of traffic for probably three weeks, and it is feared that this may result in the closing of the smelters for want of coke, the supply on hand being small. The district is completely isolated, so that normal conditions will not be restored for six weeks.

## Government's Lead Purchase

The following communication has been sent by the Lead Committee to the mine operators, smelters, and refiners of lead throughout the country: The Committee on Lead appointed by the Advisory Commission of the Council of National Defense has agreed on behalf of the domestic producers of lead to furnish 8000 tons of pig lead between now and August 1, to meet the requirements of the United States Government. The price set for this tonnage is 8c. per lb. East-St. Louis. As the probable production for the month of July will be about 48,000 tons of pig lead, this represents one-sixth of the total production for that month. If every producer agrees to furnish his share of this sale, it means that each will sell one-sixth of his July production on the basis of 8c. per lb. Are you willing to participate in this sale? If so, please advise the chairman of the Committee on Lead promptly. If you own a smelter you will receive shipping instructions from the committee for the amount which you agree to furnish. If you do not own a smelter, may we ask that you instruct the smelter which smelts your ores to furnish one-sixth of the lead-content of the ore which it accepts from you in July on this government order and notify them that you will accept in settlement for that amount of lead in your ore the price that the Government is paying. If you give such notice to your smelter, please inform the chairman of the Committee on Lead so that the Committee can make their plans accordingly and can see that your smelter is required to furnish that amount of lead to the Government at the 8-cent price. An early reply will be greatly appreciated.

CLINTON H. CRANE,

Chairman, Committee on Lead.

JAPANESE buyers are paying any price demanded in a scramble to purchase ship-plates. Recently 9.9 cents per pound was paid in order to switch 1000 tons of such material to the new ship-building Empire that evidently has dreams of becoming the world's carrier after the War. It is plain that control of supplies required in our preparations for effective warfare must come speedily if we are to do our part in resisting the common enemy. There is a serious defect in our organization when we cannot build ships to meet our own urgent needs, yet allow Japan to ship out of the country 1000 tons of ready-made ship-plate. It is important to recall in this connection, the suggestion of Great Britain that Japanese merchant vessels might relieve the pressure in the trans-Atlantic movement of supplies, which brought the soft reply that Japan would be pleased to supplant the British ships plying in Eastern waters so as to relieve them for service in the submarine zone.

BARYTES is being mined on a large scale near Pulantien, in the Kwangtung leased territory in Manchuria, by a company of Japanese resident at Pulantien. The corporation is called the Manchuria Barium Co., and is capitalized at \$25,000.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## CRIPPLE CREEK, COLORADO

LESSEES THROUGHOUT THE DISTRICT CONTINUE TO MAKE A LARGE AND PROFITABLE PRODUCTION.—NEW STRIKES REPORTED FROM VARIOUS PARTS OF THE DISTRICT.—IMPORTANT DEVELOPMENT FROM THE ROOSEVELT TUNNEL.

Block 8 of School Section 16, on the north-east slope of Bull Cliffs, is again in the producing list. Charles Eaton and associates are operating a sub-lease from the Co-operative Mining & Development Co., that holds the original lease on the school lands from the State. Eaton & Co. loaded out their initial shipment of milling ore last week. This property, the only one in the Cripple Creek district, located on school lands that is paying royalties to the State, was operated for 15 years consecutively by the late Alfred La Montaigne, a French Canadian. La Montaigne, it is estimated, took out about \$250,000 gross from above the 600-ft. level.

The Millasier Mines Corporation, operating and owning the Clyde property on the north-east slope of Battle mountain, has unwatered the Clyde shaft 800 ft. deep, with about 3000 ft. of laterals at the bottom level. The shaft is to be sunk an additional 1500 ft. G. F. Lasier of Detroit, Michigan, one of the owners, is at the mine.

The Dante mine on Bull hill, owned by the Dante Gold Mining Co. is to resume activity. The lease held by the Consolidated Mines & Development Co. is to be transferred to a new company being organized to operate the mine.

The Hahnwald brothers, Olsen & Co., operating the property of the Gold Sovereign Mining & Tunnel Co. on the southwest slope of Bull hill, are cutting a station at the 1500-ft. level. Extensive development both north and south of the shaft has been planned. The workings on the property are 1350 ft. deep.

A shipment of milling-grade ore was loaded out last week from the Coriolanus mine on Battle and Squaw mountains, by Matt Eder and Aitken of Victor, lessees, operating under lease from the Aloha Gold Mining Co., T. B. Burbridge, of Denver, president. The ore shipped was of milling grade.

The Catherine Gold Mining Co., Charles Walden, of Victor, general manager, holding a lease and option on the properties of the Last Dollar Gold Mining Co. on Bull hill, is extending a drift south-east at a depth of 1500-ft. toward the Modoc mine and on the extension of the Modoc-Last Dollar vein. The ground under development is virgin and with the value of the ore improving it is expected an orebody is near. The breast of the drift is about 600 ft. from the line so that there is ample ground ahead.

The Acacia Gold Mining Co. is cutting a station at 1350 ft. preparatory to beginning lateral work at this depth. In the meantime the company continues production from the 1250-ft. level, and lessees are operating in the levels above. About 350 tons of milling ore has been loaded out from the mine this month.

Last week a strike was reported from the 400-ft. level of the Jerry Johnson mine and during the past few days, the Cripple Creek Deep Leasing Co., operating below the 650-ft. level of the mine, has entered the downward extension of the Caley shoot at the 650-ft. level, by a raise from the 950-ft. level. Two feet of the 4-ft. vein is sampling 5 oz. gold per ton and the ore broken 3½ to 4 ft. wide will ship at 2 oz. gold per ton.

A carload settlement, under date of June 25, on 63,000 lb. net of ore from the Caley lease, was at a rate of \$46.90 per ton. The check to the lessee after deduction of freight, treatment, and royalty amounted to \$1233.19.

The Beacon & Raven Hill Gold Mining Co., owning 17 acres patented, at the Arequa townsite on the southern slope of Raven hill, has contracted 250-ft. of driving from the line of the Roosevelt tunnel, of the Cripple Creek Deep Drainage & Tunnel Co., to get under the orebody developed to a depth of 700 ft. by the Elkton Mining & Milling Co. The Beacon & Raven Hill property adjoins the Elkton mine, and that company mined a good grade of milling-ore to that depth. The work from the drainage-tunnel level, at an elevation of approximately 8100 ft. above sea-level, is being followed with interest by mining men. The lateral will cut under the ore-shoot 900 ft. deeper than any previous development in this part of the district. Low assays are already obtained from the drift, and there remains about 30 ft. to drive before the objective point under the shoot developed above is reached.

A reported strike on the 20th level of the Golden Cycle mine of the Vindicator Consolidated Gold Mining Co. was practically confirmed last week by a visit of Guildford S. Wood, president; Adolph Zank, the treasurer; George Stahl, the secretary; and Mr. Sigel, a director of the mine. From a local source it is learned that a strong orebody has been opened at a depth slightly exceeding 2000 ft. in the main shaft of the Golden Cycle mine, on one of the main veins, and the ore exposed as broken from 6 to 8 ft. wide, is all of a good milling grade, with a central strip several inches wide that may be classed as of smelting grade.

## TREADWELL, ALASKA

MINERS AT KENNECOTT STRIKE ON BEING REFUSED AN INCREASE IN WAGES.—THE TREADWELL COMPANY TAKES AN OPTION ON THE RED DIAMOND GROUP OF MINES.—EXTENSIVE PREPARATIONS BEING MADE TO EQUIP AND OPERATE THIS PROPERTY.

Two hundred miners working in the Bonanza and Jumbo mines of the Kennecott Corporation have walked out. They demanded an increase of wages of 15 to 50%, according to the price of copper. An offer of arbitration was made in behalf of the company, but it was refused and the strike followed. About half of the men have refused to strike, however, and these include the men in the shops, mills, and leaching-plant, and the construction men.

The threat to strike came several days ago and at that time the United States marshal took the situation in hand and as a precautionary measure closed the saloons at McCarthy.

The Treadwell company has taken an option on the Red Diamond group of claims adjoining its holdings on the west and will begin prospecting at once. This enterprise will create a greater demand for labor than now exists and just how that demand will be satisfied is a problem. Any kind of labor is very scarce in this part of the country, hundreds of men having left for the West and the interior within the past few weeks. Employers of labor, however, expect better conditions in the near future.

The Red Diamond property is the first to be bonded on Douglas island by the Treadwell companies with over \$1,000,000 development fund available. The property is situated

south by west of the Nevada Creek group fronting toward Stephens passage. Engineers have surveyed an outlet from back of the Ready Bullion property, which would give a passage for the ore by tram or surface railway to the company's mills at Treadwell. The Red Diamond group comprises 12 claims. Work has been carried on at various times for the past ten years, development consisting of a shaft and drifts on the orebody at several levels. A summer-camp is to be established next week at the property. In the meantime, provisions, tools, and other necessities are being delivered to the property.

P. R. Bradley, general manager, has announced that his engineers are ready and willing to investigate any property presented.

A new compressor has recently been installed at the Mineral King Mining Co.'s property at Bettles bay.

Articles of incorporation have been filed at Valdez for the Q & Q Gold Mining Co., the capital stock being \$50,000. The incorporators are Frank Cockrell, Dr. H. Cockrell, and Robert L. Hawkins. The company is organized for the purpose of owning and operating property near Port Wells.

## TORONTO, ONTARIO

HEAVY SHIPMENTS OF SILVER ORE AND BULLION FROM COBALT.—  
OLD MINES RE-OPENED PRODUCING HIGH-GRADE ORE.—HOLLINGER PASSES A DIVIDEND.—SERIOUS COAL SHORTAGE  
FEARED IN CANADA AND OFFICIAL STEPS TAKEN TO PROVIDE  
AGAINST IT.

The silver mining industry of Cobalt was never more active than at present, operators being desirous of maintaining production at the highest point in order to take advantage of a favorable market. Some 2000 men and about 200 machines are steadily employed, and despite the talk of strikes the majority of the workers are well satisfied with existing conditions. They are receiving in addition to wages a bonus of 50c. per day so long as the price of silver remains above 70c. per oz., and should it rise above 80c. the bonus will be increased to 75c. per day.

Shipments of both ore and bullion have recently been heavy. During the week ended June 16 approximately 956,404 lb. of ore was sent out with 517,666 oz. of bullion, being the largest aggregate for several months. The Nipissing maintains its lead as the largest producer. During May the company mined ore of an estimated value of \$261,668 and shipped bullion from its own and custom-ores of an estimated net value of \$405,000. Driving on the Cobalt Lake fault has been nearly completed and about 1500 ft. of the vein developed at the 425 and 520-ft. levels. With the payment of its regular 5% dividend, due in July, the total returns to shareholders made by the company will amount to \$16,240,000, being 264% on the issued capital. The production of the Mining Corporation of Canada for the present year, up to April 22, aggregated 1,400,123 oz. of silver, the output showing a steady increase.

Development work at the Ophir has resulted in the discovery of a promising 6-in. vein, carrying a small silver content, south of shaft No. 2. It will be cross-cut and developed on the keewatin-diabase contact.

The report of the Beaver Consolidated for the quarter ended May 31 shows silver in bullion, due from smelters, and in ore bagged aggregating 252,948 oz. and \$49,915 cash in hand. High-grade ore and mill-rock are being recovered from orebodies on the 400 and 600-ft. levels. A raise has been driven for 100 ft. on the vein at the 1600-ft. level. The demand for mining machinery for new prospects in Northern Ontario, which cannot always be filled promptly by the manufacturers, has created a market for the disused equipment of many of the closed-down properties of Cobalt and some of these small plants, which were considered as of little value, have been sold at good prices.

The Gowganda silver area has been attracting a good deal of attention, largely on account of the size and richness of the vein found on the Miller Lake-O'Brien. The Reeves-Dobie property has been re-opened with encouraging results, and high-grade ore is being sacked. The T. C. 177 company is developing a property adjacent to the Miller Lake-O'Brien and will sink to the 300-ft. level. At the Silverado machinery is being installed. Power for this district will be obtained from Hanging Stone Falls, but construction has been considerably retarded on account of labor shortage.

Though the labor situation in Porcupine and the outlying gold district is not yet altogether satisfactory, some improvement has been effected by bringing in laborers from other points. The Dome Mines is continuing operations as well as its reduced forces will permit, attention being principally centred upon the cross-cut at the 700-ft. level to open up a large high-grade orebody discovered at that depth by diamond-drilling. It is stated to be 120 ft. wide with an average of \$17 per ton, and is expected to be reached early in July. Hitherto the average grade of the mine has been below \$6 per ton.

The Hollinger Consolidated has passed the dividend due this month. President Timmins states that this action was taken owing to the uncertainty of labor conditions and the difficulty of securing enough men for underground work to mine sufficient ore to keep the mill in operation. The directors are considering the advisability of devoting all efforts to development so long as present conditions continue and to put the mine into a position to considerably increase the output as soon as an adequate supply of labor becomes available. The suspension of the dividend will enable the company to wipe out the deficit of \$174,184 and establish a cash surplus. Construction work on the new mill has been suspended except so far as contracts already let are concerned.

During May the McIntyre milled 15,064 tons of ore of an average value of \$9.83 with a total production of \$142,476. The West Dome Consolidated has completed 1200 ft. of workings on the 300-ft. level and it is estimated that between 60,000 and 70,000 tons of ore of an average grade of \$9 per ton has been blocked out. The policy of the management is to confine operations to this level and create a large ore reserve for the proposed mill.

At the 200-ft. level of the Kirkland Lake mine a 4-ft. vein carrying high-grade ore has been discovered. It is believed to be the vein of the Wright-Hargreaves and the Teck-Hughes. The Lake Shore mine lying between these two will also benefit by the find. Construction work on the new Lake Shore mill is being pushed.

The question of providing against a serious coal shortage during the coming winter is receiving much attention from the Canadian government and the municipal authorities. The situation has become much more threatening since the United States declared war, as, owing to the increased home demand with a diminished supply of labor and a lack of adequate transportation facilities, a great shortage of the importations from the American coal mines, on which Ontario and a large part of the West are dependent for food, appears inevitable. Many municipal bodies are endeavoring to arrange for supplies to be stored as a provision against a winter coal-famine, but so far with little success. The Canadian government has appointed C. A. Magrath, of Lethbridge, Alberta, a prominent Western man, as fuel controller with full powers to regulate the price and distribution of coal, encourage increased home production, and arrange for importations. It is hoped that at least he will be able to prevent undue accumulations of coal stocks, and to check extortionate prices. Dr. Ruttan, of the Advisory Council of Industrial and Scientific Research, announces that their investigations have resulted in a discovery which will solve the problem as regards Western Canada. The extensive lignite deposits of Saskatchewan, he claims, may be made commercially valuable by a process of

briquetting, which will produce a fuel nearly equal in heating power to anthracite at about two-thirds the cost of coal in the West. The Advisory Council has asked the Government to devote \$400,000 for the construction of a plant in which the briquetting process can be carried on.

### PORCUPINE, ONTARIO

LABOR TROUBLES ARE BEING GRADUALLY BUT QUIETLY ADJUSTED THOUGH ALL OF THE OPERATING MINES ARE IN NEED OF MORE MEN.

Within the past week much of the uncertainty that for many weeks has characterized the labor situation in the Porcupine district has been cleared up. It is rumored that the strike vote taken Sunday, June 14, resulted in a majority of more than 300 against going out on strike. However, the officials of the union are keeping the returns to themselves. As yet, no definite arrangement has been reached at any of the producing mines, except the McIntyre-Porcupine and Dome Lake. The former company has granted a 50-cent increase to meet the high cost of living, and appears to have clear sailing. Dome Lake has granted an increase almost equal to that of the McIntyre, but it is understood the increase does not cover every branch of labor at the mine. At practically every mine but the Hollinger Consolidated, the employees have taken action, independent of the Miner's Union, and by forming themselves into committees representative of the particular mine at which they are employed, have approached the management, that in turn has in every instance given consideration to these requests.

It is the opinion that within a few days most of the producing mines will have taken action similar to that of the McIntyre-Porcupine.

The most peculiar fact about the situation is that at Timmins and South Porcupine reports are current that certain companies have granted an increase. These reports sometimes are convincing, but when investigated appear to have as yet no foundation in fact.

Hollinger Consolidated, although with only about half enough men available, is operating as aggressively as circumstances will permit. Outwardly there would appear to be no difference about the mine from a few months ago, when operations were at the maximum, but the tonnage coming from below speaks plainly, and convinces one that inwardly present working forces are not anywhere near the requirements. However, despite the fact that the regular disbursement of dividends at the Hollinger have been discontinued, it does not by any means signify that this mine has taken second place to any other gold mine in the Dominion. In fact, with present reduced forces, the net profit-earning power of this company is still greater than any other gold or silver mine in the country. April figures showed net profits of \$194,000 for the four-week period.

McIntyre-Porcupine is perhaps in the most enviable position of all the Porcupine producers, in that the company has very little construction work pending, and at present has a full complement of men. Operations at this property are going with greater speed than ever before. The tonnage treated sometimes rises to 550 tons per day, and the monthly average is well above 500 tons per day. Mill-heads range from \$7 to \$15. This is due to the fact that the management is not endeavoring to establish an average grade, but is taking run-of-mine ore, and anything containing \$2 per ton and upward is being sent to the mill. The average grade of ore treated within the past 12 months has approximated \$10, while the average throughout the mine is about \$12.50. Preparations to carry development work first to the 1300 and then to the 1600-ft. level are now under way. The most interesting development at the mine recently is that the main orebody at the 1000-ft. level has now widened out to 52 ft. and is high-grade milling ore. The

face of the main drive is now within 20 ft. of the Jupiter line.

Mill-construction at the Schumacher is proceeding. About 80 men are now on the pay-roll as compared with a desired force of 120. The old mill is running at a capacity of about 100 tons daily and mill-heads are now up to around \$10 per ton.

Porcupine V. N. T. is working about 90 men and here also the mill is treating about 100 tons of ore per day. Developments underground are proceeding satisfactorily. At the 600-ft. level the main vein is 22 ft. wide of a good milling grade of ore.

Porcupine-Crown now has about 90 men employed, and is maintaining production satisfactorily.

### COBALT, ONTARIO

PRODUCTION BEING FORCED UNDER THE STIMULUS OF THE HIGH PRICE OF SILVER.—LABOR AGITATORS CONTINUE THEIR EFFORTS TO BRING ABOUT A STRIKE, THOUGH THE MAJORITY OF THE WORKERS ARE SATISFIED.

Operations at the producing mines of Cobalt were never conducted more vigorously than at present. Over 2000 men and about 200 machines are employed. The high quotation for bar-silver is undoubtedly the main reason for the keen desire to force production to the maximum. The mine-workers are all receiving a bonus of 50c. per day when the price of silver remains above 70c. an ounce. This, in itself, has, to a certain extent, won the good-will of the workers. However, should silver rise to over 80c. an ounce the bonus will be increased to 75c. per day. With a 75c. bonus the workers would be receiving considerably more per day than that outlined under the wage-scale now demanded. Under the present system the workers are able to share the prosperity of the mine operators, and the married men, together with the efficient workers, would apparently not welcome any change in the present form of pay. The agitators in the union are largely unmarried men with little responsibility.

During the first week of June a total of nine cars of ore containing approximately 682,210 lb. of ore was sent from Cobalt. Bullion shipments for the corresponding period totalled \$114,063.

The report of the Mining Corporation of Canada for the first 16 weeks of the current year shows that a total of 1,400,123.96 oz. of silver was produced having a value of \$1,000,000. Total dividends paid to date by this company are \$1,711,875.

The usual quarterly dividend of 5% has been declared payable July 20 by Nipissing Mining Company, a disbursement of \$300,000, and the third dividend of this amount to be paid during the current year. The total paid by Nipissing to date is \$16,240,000, or equal to 264% on the issued capital of the company. The financial statement of June 2 shows cash in bank \$1,255,034; ore and bullion in transit, \$351,860; ore and bullion on hand, at the mine, \$853,614; making a total of \$2,460,508.64.

The Temiskaming has also declared a dividend of 3%, payable July 16 to shareholders of record June 30. This disbursement amounts to \$75,000 and is the second dividend during the current year. Temiskaming has now paid a total of \$1,834,156.25, which is equal to 74% of the issued capital stock of the company. Generally speaking, the labor supply at Cobalt is comparatively satisfactory.

### SUDBURY, ONTARIO

EXPERIMENTS BEING MADE AT IRON MOUNTAIN SAID TO BE SATISFACTORY.—A NEW MILL COMPLETED AND RUNNING.—LARGE MASS OF IRON ORE AVAILABLE.

Iron Mountain, in the Sudbury district, is receiving a thorough test, and results so far obtained are said to be satisfac-

tory. About 150 men are employed, and should the experimental work now going on justify it, the number probably will be increased to 1000 men. A mill with a capacity for 300 tons of ore per day has been installed and preparations for the concentration of ore are about completed. Mining is done by glory-hole method, and the ore is loaded direct into a train of cars and conveyed to the mill. The mill concentrate is shipped to smelters.

The Iron Mountain iron deposit is understood to contain at least 7,000,000 tons of ore. The deposit is situated four miles from Milnet Junction on the main line of the Canadian Northern railway. A spur-line has been built to the mine. Later on the facilities for iron ore production will probably be greatly increased.

### ELDORA, COLORADO

LARGE OUTPUT OF TUNGSTEN FROM NUMEROUS LEASES ON PROMINENT MINES.—MILLS RUNNING AT CAPACITY AND EXTENSIONS BEING MADE.

The Vasco company at Tungsten, which has been steadily operating its mines and mills through the winter, sees a continuation or even an increase in its prosperity this summer. The company's large mill is working at full capacity to handle the continuous shipments from over 12 different workings on the Vasco property. Shipments range from 3 to 50% tungsten, with an average of about 10%. Fred Barrett, one of the oldest mill-men in Boulder county, is superintendent of the mill. Fred B. Copeland, of the Copeland Sampling Co., in Cripple Creek, is in charge of the sampling for the company.

H. S. O'Neil and Harry O'Day are leasing on the Vasco No. 3. Bradford Black has leased No. 4, and is now clearing out one of the old stopes. No. 5 has been taken by John McKenna, who is doing exceptionally well. Cox and McKenzie have leased No. 6, and Thomas McGrath No. 7. John Walsh is leasing No. 8, and has been making regular shipments for some time. George L. Holland and associates have made the No. 10 tunnel the largest producer on the Vasco at the present time. J. B. Newham on 12, and Petro & O'Day on 13, are doing fine.

The change of this district from the Stevens Camp, of a little more than a year to the prosperous little town of Tungsten can hardly be realized. Great credit is due the Vasco company in opening up this district.

Tom McGrath has a position with the Morgan-Tungsten Mining Co., where he is superintendent. He was until recently with the Vasco people in the same capacity. This mill was recently taken over from Diggs and Clark. Verne Collins has a position with the Boulder Products Company.

The Clark tunnel, at Tungsten, has cut two veins and has leased them both. The Clark mill is running nearly to full capacity, and is receiving a good supply from nearly all the workings on the Clark property. Ex-sheriff Baxter is leasing on the Clark No. 1 and has been making steady shipments. Dan Gillett and Goddard are working the Clark 3, and taking out a good grade of ore regularly. Jacob Wade reports he has made a big strike on the Clark No. 5.

The Caribou mill at Caribou, Colorado, has been shut-down and will suspend operation as soon as it runs the ore on hand. It is reported that this is due to some dispute about the water-rights. Walter and Humphrey are preparing to wash the dump at the Vasco 6, on the Clark property. This is one of the richest Vasco dumps and is sure to pay well.

President Howe, of the Keystone Mining & Milling Co., at Magnolia, Colorado, visited the company's property this week. Manager Clifford Staley has been repairing the mill and adding to it. A. Ganvey, of Farmersville, Ohio, reports success from the Doss mine at Wallstreet that he recently leased.

C. A. DeWitt, superintendent of the Wolf Tongue mill at Nederland, reports the mill running to its fullest capacity.

The biennial report of the Colorado State Bureau of Mines

in district No. 1, Boulder county, contains a résumé of the mining situation and conditions here. The Colorado State School of Mines will re-open in the fall as usual.

Woodring and Dupont, on the Huron, at Eldora, are steadily pushing development work. The Dixie mine above Lake Eldora has let a contract and work will be started at once on this property.

### KIRKLAND LAKE, ONTARIO

THE IMPORTANT GOLD MINES OF THIS DISTRICT.—LARGE AMOUNT OF HIGH-GRADE ORE IN SIGHT IN THE VARIOUS MINES, AND FURTHER DEVELOPMENT PLANNED.

Second in importance of the quartz-gold mining districts of Canada is Kirkland Lake that already is yielding upward of \$1,000,000 in gold annually.

The Tough-Oakes is the pioneer and the premier mine of the district and is equipped with the largest mill. The ore at this mine is considerably higher in value than at any other gold mine in any of the Northern Ontario gold districts. It is true that costs are comparatively high, due chiefly to the hardness of the rock, but the high average gold content of the ore allows a large margin of profit and a handsome surplus for dividends is piling up. The regular dividend paid by the Tough-Oakes company is  $2\frac{1}{2}$ % quarterly. During 1916 the company paid a total of \$260,750. The ore reserves of this mine are estimated at upward of \$1,000,000.

The second gold producer of the district is the Teck-Hughes, which only recently installed a ball-mill having a capacity of 75 tons of ore daily. The result of the first month's run, which is understood to be satisfactory, will probably soon be made known. The ore reserves of this property are said to be sufficiently large to warrant a further addition to the milling equipment, that is, provided the amount of labor available were to become normal. The ore throughout the mine is of comparatively high grade.

The third producer will be the Lake Shore mine. Already on this property there are upward of \$500,000 worth of ore blocked out, and a new 75-ton mill is being transported to the property. Recently a new vein 4 ft. wide and carrying remarkably rich ore was discovered in a cross-cut underneath the lake at a depth of 200 feet.

The property of the Kirkland Lake Gold Mines Ltd. may be considered as the fourth in importance. This property has been opened to a depth of 600 ft. and approximately 5000 tons of \$10 ore has been blocked out. About 5000 tons of good milling ore has been accumulated on the dumps. The lower workings of this property are the deepest in the Kirkland Lake camp. The president of the company has intimated that the property is about ready for a 100-ton mill.

The Wright-Hargreaves is another valuable property, although occupying fifth place in point of development work done and ore reserves blocked out. It is, nevertheless, considered as one of the leaders of this district. The main vein has been traced for something like 3000 ft. and at all points where opened up contains a high average gold content. At the 100-ft. level of No. 2 and 3 shafts, the grade of ore is said to range around \$30 per ton across a width of 12 ft. The treasury of the company is in excellent shape, upward of \$100,000 being on hand, and development will be continued to the 300-ft. level of both shafts, where a 90-ft. drift will be driven to connect the two workings.

For the time being, work on the La Belle Kirkland has been suspended. It has been developed to a depth of 350 ft., and a large tonnage of good-grade mill-ore has been blocked out. Also, as a result of 5000 ft. of diamond-drilling, done during the past winter, ore has been indicated to a depth of about 700 feet.

All the properties mentioned are either producers, or considered as probable producers.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—About 200 men at the Jumbo and Bonanza mines of the Kennecott Mining Co. walked out on a strike on the morning of June 16. This is about half the number of men on the pay-roll, and includes all the miners and shovelers, the tramway-men at the upper stations, and the Japanese cooks at the mines. The strikers are demanding an increase in wages of from 18 to 50%. The walk-out is confined to the mines. The employees at the lower camp, machine-shops, mill, leaching-plant, and those engaged in construction work refused to join the strikers. All the strikers left peaceably after being paid off and have gone to Blackburn, four miles from Kennecott.

A demand was made by the men for higher wages and but three days was given to the management to accede to the demand. E. T. Stannard, the manager, is on his way to New York, and H. D. Smith, assistant manager, lacking authority to grant such a demand, requested of the men a reasonable time in which to lay the matter properly before the New York officials of the company.

Any additional time was refused by the men, as well as an offer to arbitrate and also a proposal to have Mr. Stannard return immediately for conference with the men.

On two previous occasions during the last year the employees at the Kennecott mines have made demands for increase in wages upon short notice, but in each instance sufficient time was given in which to refer the matter to the New York office and the demands were either met in full or otherwise amicably settled.

It is not claimed by the men that the company has not fairly lived up to its part of these former agreements.

The demand now made is for \$5.75 per day with \$1.25 off for board, for miners and shovelers with even a greater per cent increase for cooks.

The scale at the mines at the time of the walk-out this morning was as follows:

Base-rate for miners \$4.25 per day, and for shovelers \$3.75 per day, with \$1.25 off for board, plus the following bonuses:

Copper between 18 and 20c., 25c. per day; between 22 and 26c., 50c. per day; between 26 and 30c., 75c. per day; over 30c., \$1 per day. The local officials of the company insist that the men have not lived up to their former agreements, and that they are not fair in refusing to allow a reasonable time for the company to consider their demands.

United States Judge Fred M. Brown, of the Third Division of the District of Alaska, has ordered all saloons closed at McCarthy, which is five miles from Kennecott, and is the nearest town to the mines in which saloons are allowed.

United States Marshal Brenneman is on his way to McCarthy to take personal charge in case of any violence or disorders.

Cordova, June 16.

(Special Correspondence.)—The Alaska Treadwell Gold Mining Co. has taken a working-option on the Red Diamond group of claims, situated near Bullion creek, on Douglas island. Development work on the group will start at once. The claims are owned by the Winn interests, of Juneau.

Juneau, June 17.

The Shelekoff Mining Co. has shipped machinery to its mines on Kodiak island. The property consists of seven copper claims situated near the head of Kuliak bay.

## ARIZONA

### GILA COUNTY

The Inspiration Consolidated Copper Co. at Miami has issued the following circular letter:

Miami, June 29, 1917.

To the employees of the Inspiration Company: The following communication is being presented to the various operating Companies of this district by a Committee of the Local Miners' Union:

June 28, 1917.

"Dear Sir:

"Resolved that we request a conference with the representatives of the mining companies of the Globe-Miami District for the purpose of discussing the following demands of the local unions of the International Union of Mine, Mill and Smelter Workers of America.

"No. 1. Recognition of the Grievance Committee of the Local Unions of the Mine, Mill and Smelter Workers International Union, and those of the other organized trades now represented in the mining industry in the Globe-Miami district.

"No. 2. Representatives of the unions to be allowed on company property at any time for the purpose of organization, it being understood that such representatives will in no way interfere with men in the discharge of their duties.

"No. 3. Reinstatement of men discharged for cause other than incompetency, competency or incompetency to be determined jointly by the Grievance Committee of the unions and representatives of the companies. The spirit and intent of this clause is that no man shall be discharged or refused employment on account of personal prejudice or on account of activities in union affairs.

"No. 4. Equal representation on the Board of Control of the Hospital.

"We request an answer by 10 A.M. Friday morning, failing to receive an answer accepting or rejecting these demands, a strike vote will be taken on Saturday, and if carried, a strike will be called on Monday morning at 7 A.M."

The Inspiration Company deems it proper, at this time, to advise its employees, labor organizations, and the public at large, of its position on the subject of meeting with delegations from labor organizations or recognizing committees from those bodies in its operations.

First and foremost, we reserve the right and privilege to conduct our own affairs. We have always respected the rights and principles of Union organizations and their members, and have never attempted to disrupt these organizations or to discriminate against any of our employees because of their affiliation with the Union. On the other hand, we have always recognized the rights of those who did not care to join these organizations. This policy will be maintained in the future.

There appears to be no need of any conference with outside labor organizations. If the matters which they wish to bring to our attention concern our employees, the men have a representative Committee elected by themselves, through which such matters, whether they be complaints or suggestions for improved conditions or service in any department, can be brought to the management. If the matters which they wish to discuss concern recognition of the Unions, we say, frankly and with full knowledge of gravity of the situation, that we will recognize no such labor organizations or delegations from

them, and that we will grant no demands for recognizing Union Committees.

In short, if we are to continue to operate it can only be possible if we are allowed to conduct our own affairs with the help and suggestions of our own employees.

INSPIRATION CONSOLIDATED COPPER CO.

By C. E. MILLS, Gen. Mgr.

Metal Mine Workers' Industrial Union, No. 800, affiliated with the Industrial Workers of the World, formulated its demands on the evening of June 29 for presentation to the managers of the three big copper companies in the district, says the *Arizona Record* of June 30. The demands are identical to those which have been made by striking miners at Butte and Bisbee.

According to a representative of the metal workers, this organization will hold a mass-meeting tonight at which time, unless the demands are met by the companies, a strike vote will be taken. If they are refused, the members will possibly quit work Sunday night or Monday morning.

Following is the official statement of demands which was issued:

"Miami, Arizona, June 29, 1917.

"Mine Managers of the Globe and Miami District:

"We, the joint committees of the Metal Mine Workers' Industrial Union, No. 800, present the following demands:

- "1. Two men to work on all piston and Leyner machines.
- "2. Two men to work together in all raises.
- "3. No blasting in stopes, drifts, or raises during shift.
- "4. Abolition of the 'rustling-card' system.
- "5. Abolition of the contract-bonus system.
- "6. Abolition of the sliding-scale.
- "7. Water-sprays shall be used on all machines.
- "8. No discrimination against any member of any union.
- "9. Representation in the control of hospital.
- "10. Minimum wage of \$6 for all men working underground.
- "11. Minimum wage of \$5.50 for all men working on surface.

"Respectfully submitted,

"METAL MINE WORKERS' INDUSTRIAL UNION No. 800."

The local authorities at Miami claim that the strike situation has gone beyond their power of control, and the War Department at Washington late on July 3 instructed the Southern Department to take the steps necessary to handle the situation, and troops will be sent into the mining districts where needed if the request is officially made by the authorities in Arizona.

#### CALAVERAS COUNTY

(Special Correspondence.)—The Sheep Ranch mine, after a long idleness, is to be reopened by New York capital under the direction of H. R. Plate, of New York. The mine has been worked to a depth of about 1200 ft. and for many years was a large producer. The ore was free-milling and often was filled with visible gold. Ore of this character was generally of dark bluish color and was in demand by jewelers who converted the rock into various forms of jewelry. The vein was about 18 in. wide and the average of the ore for years was about \$15 per ton.

Sheep Ranch, June 24.

(Special Correspondence.)—The Maypole mine, formerly known as the Shear mine, has been re-opened by L. G. Blakemore. The mine is half a mile north-west of Mokelumne Hill, at what is known as the Italian gardens. The claim, which is 2700 ft. long, is located on a north-east south-west vein that dips north-west in greenstone schist. The quartz is 6 ft. wide at the face of the old tunnel, which has been cleaned out by Mr. Blakemore. It was caved throughout its entire length, having been idle and forgotten for more than 30 years. On the dump was 300 tons of rock that sampled \$5 per ton, which was considered good enough to justify an examination. By driving 300 ft. farther there will be available from 350 to

400 ft. of backs. The outlook for this old property, one of the first, if not the first, quartz claim located in this county, is considered promising.

The old Boston (Esperanza) mine is to be re-opened by a Mr. Baker, who it is reported has made a payment of \$17,500 on the purchase price. This mine has been extensively worked in years gone by and has had not less than three mills, and at one time a chlorination works. The vein is large, 40 to 60 ft. wide, and consists of a zone of silicified amphibolite schist. It carries 2 to 10% auriferous sulphide, together with free gold, but is low grade and requires careful and economical handling.

The Gardella brothers have closed the sale of their Garibaldi mine in the Mill Valley district to W. M. Stiver, who represents San Francisco capitalists. The mine is seven miles from Mokelumne Hill. A company has been organized to operate this property, which will be known as the Garibaldi Mining Co. There is a shaft 100 ft. deep in which some good ore has been found. Machinery will be placed on this property by the new owners.

Mokelumne Hill, June 24.

(Special Correspondence.)—There is much prospecting being done about Railroad Flat, and some good discoveries are announced. The district is one of many possibilities. It was only a few years ago that the Comet mine was discovered, almost by accident, and within a short time produced \$125,000 at large profit. There are a number of old mines, at one time substantial producers, that are again being investigated.

Railroad Flat, June 24.

(Special Correspondence.)—The Utica mill has been closed-down for a week because of an unusual flow of salt water, but is about to resume operations. The Angels Quartz mine has been thoroughly cleaned up and is now ready for a long period of activity.

Angels, June 24.

(Special Correspondence.)—The proposal to re-open the Blazing Star has been abandoned, it is stated, owing to the War. The Sawyer mine, controlled by William Foltz of Seattle, is about to resume operations, San Francisco capital having been interested, it is reported.

West Point, June 25.

#### DEL NORTE COUNTY

(Special Correspondence.)—Tom Galvin, who is representing the American Exploration Co., which is operating chrome properties on French hill and Low divide, expects to spend many months here. There now is 8000 tons of high-grade chrome ore ready for shipment. This week the company expects five auto-trucks with which to haul the ore to this place. It will be shipped by steamer to San Francisco.

The Duley and Lauff copper property on Patricks creek is developed by many hundred feet of adits. Work has been suspended for some time and an Eastern company that has examined the property now contemplates its purchase. O. B. Lauff and West Duley are hotel owners of this place.

Large deposits of chrome ore have been found and located on Diamond creek by G. W. Gravin, and other large deposits have been found and located on Cedar creek by John Taggart, in this county.

Crescent City, June 23.

#### SISKIYOU COUNTY

(Special Correspondence.)—John Hays of Gold Hill, Oregon, and Charles Moon, of Hornbrook, left for their gold quartz mine, 8 miles from Hornbrook. They discovered the vein several years ago and from time to time have done considerable development work, and now are preparing to erect a small mill on the property. The ore is rich and free-milling, but is only 8 to 10 in. wide, where uncovered.

Mike G. Womack, of Medford, Oregon, and M. A. Carter, and

L. D. Corbitt of Ashland, Oregon, have a promising gold prospect, the Golden Gem, which is situated 16 miles west of Hiltz on Hungry creek. They discovered the vein last year and have done enough work to justify the further development of the property. On account of the inaccessibility of the wagon-road to the mine they contemplate erecting a small mill on the property. The ore assays \$70 per ton of gold and is free-milling. The vein has a width of 6 to 22 in. There is several hundred feet of work on the property, though the greatest depth attained on the vein is 70 feet.

Mr. Womack and his associates will resume operation on a vein of gold, silver, and galena situated 16 miles west of Gazelle, in the Etna Mills district. The vein is in limestone and averages 10 ft. wide. On account of the distance to a shipping-point the owners are contemplating erecting a mill on the property this season and reducing the ore to concentrate for shipping.—Work has been resumed on a number of old quartz properties in the Hornbrook district.

Hornbrook, June 25.

## COLORADO

### BOULDER COUNTY

(Special Correspondence.)—C. E. Brandenburg, on Left Hand, has made a shipment of gold ore from his new discovery that seems destined to prove a bonanza. This discovery is one of the best that has been made here in years. The vein is from 3 to 4 ft. wide with a rich streak from 10 to 12 in. of solid copper-iron.

Cowdry & Co. has leased the Sunday mine at Rollinsville and will start operations on a large scale.

Frank Arondel, of Nederland, reports that the Last Chance has 3 ft. of good tungsten ore.

Eldora, June 26.

### TELLER COUNTY

(Special Correspondence.)—The directors of the Granite Gold Mining Co. declared a dividend of 1c. per share on the issued stock of the company, payable July 5 to stockholders of record June 26. The amount of the dividend is \$18,500. The company now will go on a bi-monthly dividend basis. Previous to this new dividend the last disbursement was that of November 1912.

Cripple Creek, June 26.

## MONTANA

### GRANITE COUNTY

(Special Correspondence.)—The manganese mines of the Flint Creek district, which is just east of Philipsburg, are producing from 200 to 400 tons of ore per day; the Philipsburg Mining Co. is shipping from 50 to 100 tons per day; the Mullins-Hynes property, from 60 to 100 tons; the Courtenay lease, from 50 to 60 tons; the Cape property, 25 to 50 tons; and other mines varying amounts. Philipsburg, which has been a silver-producing camp for 50 years, has awakened to the possibilities of her manganese deposits, and it is believed this district will produce more manganese this year than any other district in the United States.

W. C. Phalen, of the U. S. Bureau of Mines, has just paid a visit to the mines here and states that he has actually seen more manganese here than at any other place in the United States.

Most of the ore is being shipped East and a 45% ore will net at the mines at present \$30 per long ton.

Philipsburg, June 25.

### SILVER BOW COUNTY

Miners at Butte are interested in the discovery of a large body of manganese ore in the Hibernia mine of the Davis Daly company. The orebody is 100 ft. wide, and between 700,000 and 1,000,000 tons of ore is in sight. It is close to the surface and can be handled by open-cut method.

W. L. Creeden, general manager for the Davis Daly company, has gone East to close contracts for the disposal of this ore. Two of the largest steel companies are negotiating for the entire output. Arrangements have been made by the Davis Daly company with the Butte Detroit company by which the latter will handle the ores at Butte. In addition to the orebody on the Hibernia claim, a body of manganese has been found in the New Republic claim, which also belongs to the Davis Daly company. This body of ore is said to exceed in size that in the Hibernia. The opening of these two bodies of manganese has started a hunt in scores of claims in the West Butte district.

## NEVADA

### CLARK COUNTY

(Special Correspondence.)—The Duplex mill is running on ore from the J. E. Griffith lease on the Duplex mine, and there is no indication of a shut-down, as other lessees are getting out good ore.

George Colton, one of the owners of the Duplex mine, and who is now leasing, says that Jack Ellison, one of his employees, has opened a fine body of rich ore. Several carloads recently shipped ran well in gold, copper, and lead.

Wells, Lind, and Ray, who are operating the Searchlight Mining & Milling Co.'s property, have shipped a large tonnage of good lead ore. Two cars shipped recently to the smelter returned \$18,000, and during this period several hundred tons of good milling ore was also produced by them. They found a new vein of rich ore a few days ago.

The mill of the Chief of the Hills company is nearly completed, a test run having been made to ascertain what changes, if any, would be advisable. Ben Stevens is superintendent.

Searchlight, June 23.

### EUREKA COUNTY

(Special Correspondence.)—Thomas Brown and associates, of San Francisco, have taken a bond on the Holly mine of this place and will commence work July 1. The Holly is fully equipped with a 60-hp. gasoline-hoist and arrangements have been made to get distillate from a carload just shipped in for the Connelly mine.—A body of shipping ore has been opened up and two and a half tons per day is being taken out of the Will Heubner property, recently purchased by A. G. Burritt, of Salt Lake City. This property adjoins the California. It is expected that as soon as the development work now being done is completed large orebodies will have been found, as the ore becomes larger, richer, and better as work progresses.

Eureka, June 24.

### HUMBOLDT COUNTY

(Special Correspondence.)—The Adams vein on the 800-ft. level of the Rochester mine, at Rochester, has widened to 14 ft. Much of the ore is high-grade with free gold and native silver showing plentifully. Drifts are being extended from the 900-ft. level in expectation of intersecting the Adams vein. The East vein is yielding good ore on the 700, 800, 900, and upper levels. The mill clean-up for the last half of May yielded \$26,943.

Superintendent Wilkey, of the Rochester Combined Co., expects to have mill-grading completed by July 10 and construction of the plant started. Over 100,000 ft. of lumber has arrived and considerable machinery is daily expected. A 160-ft. raise has been started from the main working-tunnel in the Shepherd claim to connect with No. 1 level. The main tunnel is in 480 ft. and has entered good ore. The Maynaugh tunnel, on the Happy Jack, has also entered excellent ore about 380 ft. from the portal. Developments are proceeding rapidly on the Bacchus and Happy Jack claims.

New work has begun on the 1600-ft. level of the Seven Troughs Coalition. The main drift is advancing toward the shoot, which yielded specimen ore in the upper workings. Good ore is being mined above this point.

An orebody ranging from 4 to 12 ft. wide has been opened in the Cheefoo mine, at National. All the ore is stated to be of good milling grade with streaks showing silver sulphide and native silver. A little gold occurs. Construction of mine buildings is proceeding. N. P. R. Hatch is general manager. J. C. Sullivan and H. L. Schreck, of San Francisco, are heavily interested.

A new mill is in operation at the Buckaroo mine, in the Pine Forest district. Developments have been proceeding for several years and a large tonnage of good ore is stated to be in sight. The mine is 12 miles north-west of Quinn River crossing, and is operated by the Oklahoma Gold Mining Co. Thomas Ewing is general manager.

Ore averaging \$250 per ton in gold and silver is being shipped from the 700-ft. level of the Seven Troughs mine, at Vernon, and on the dumps a large tonnage of \$25 ore is being placed with a view to treating it at the mine. From the winze on the 800-ft. level a cross-cut is advancing in promising territory.

Lovelocks, June 28.

#### NYE COUNTY

(Special Correspondence.)—Foundations are being placed for the auxiliary power-station of the Tonopah Extension, and by August 1 it is believed the plant will be ready for service. Its completion will be the signal for resumption of work at the Great Western and Tonopah Bonanza mines with three shifts, and extension of the deep cross-cut of the Western Tonopah Co., controlled by Boston and Butte capitalists. This work is designed to determine the possibilities for ore in the extreme western part of the district.

The mill clean-up of the Tonopah Extension for the first half of June yielded 31 bars of bullion valued at \$58,000. Most of the ore is coming from No. 2 shaft workings, but as soon as the auxiliary power-plant is in operation a heavy output from the deep levels of the Victor shaft is planned.

The Tonopah Belmont Co. expects to have the mill at its Surf Inlet gold mine, on Princess Royal island, above Vancouver, B. C., in operation about August 15. Mine conditions are reported highly satisfactory. Work on the adjoining Pugsley property is proceeding steadily. It is stated the Eagle-Shawmut mine, near Sonora, California, is also developing satisfactorily. The company reports net earnings for May at \$98,525, exceeding the April net earnings by over 15%. The Jim Butler reports May profits of \$44,136, and a total of \$191,956 for the year. The weekly output is about 700 tons.

Tonopah, June 28.

(Special Correspondence.)—Shaft sinking in the White Caps has reached a depth of 110 ft. below the fourth level. The fifth station will be cut after a lift of 127 ft. has been made, and as the fourth level is 436 ft. below the surface, the next level will have a vertical depth of 563 ft. The water from the several faces in the workings has steadily diminished during the week. The ground cut in the shaft-sinking is silicious shale and is the hardest known in the camp, and for this reason the footage made during the week has not broken any records. In the west drift on the third level 15 ft. has been made during the week, with no water encountered. The bulkheads and flood-gate are in place in the east drift and as the water now only approximates 75 gal. per minute the drift will be extended. It is the intention to commence the filling of the ore-bins during the first week in July, preparatory to the mills starting. In the mill five hearths of the Wedge roaster have been completed and the bricklayers are at work on the sixth. The crusher-house has been completed and machinery installed. The tightening of the mill-tanks after being filled with water is in progress. The landing-platform and trestle from the head-frame to No. 1 ore-bin is nearing completion. A large-size Steele Harvey tilting-furnace for reducing the gold precipitate has been received and is on its foundations in the refinery. The cut-off wagon road from the White Caps to

Pipe Springs has been completed and is in use, both to the White Caps and the White Caps Extension.

At the shaft of the White Caps Extension five car-loads of lumber are coming in for the mine buildings, employees' bunk-house, and superintendent's house. The shaft will be the largest in the district, having three compartments. Grading for the buildings is in progress. An air-line has been laid from the White Caps to furnish air for the rock-breaker, until the Extension's compressors arrive. Three 50-kw. transformers have arrived for the mine. It is expected to purchase the necessary hoisting machinery at Goldfield, and a double-drum hoist will be brought in immediately.

At the Union Amalgamated the face continues in hard blue lime. The east drift from the north cross-cut has exposed one foot of ore averaging \$100 per ton in gold. This probably is the continuation of the Bath ore-shoot, that in the upper part of the mine yielded many thousand dollars to lessees. No. 2 cross-cut raise has been started to reach the ore left in the hanging wall of the west drift, 110 ft. west from the shaft. It was found impracticable to carry all of the vein in the drift at this point. In the raise is 4 ft. of ore of milling grade, which makes the vein 8 ft. wide at this point. Since the above was written, further development shows the ore in the new orebody mentioned as the probable continuation of the Bath orebody to assay \$176.

Rapid progress is being made in sinking the shaft of the Extension company below the 100-ft. level. An average of four feet per day has been made in the sinking, with one shift of miners. The vein has opened out as the shaft is being sunk from 16 in. to over 3 ft. It is the intention to continue the shaft-sinking to a depth of at least 100 ft. farther before exploring the medium-grade ore-shoot developed on the 100-ft. level.

At a depth of 110 ft. water was struck in the Red Top shaft. For a few days an endeavor was made to keep the flow down by bailing, but this has been found impracticable, and to prospect the lime belt, a drift on the lime-shale contact has been started to the north-east. Gold was found and the drift is being extended. The management has ordered a three-drill compressor.

The installation of new machinery has occupied most of the time at the Morning Glory recently. The new hoist has been connected up, and the buildings have been erected. Installation of the compressor is proceeding. In the No. 3 shaft-sinking all of the rock taken out is pay ore. The average value for the last 10 ft. of sinking has been \$10 in gold.

The drift on the 300-ft. level of the Manhattan Consolidated is out 200 ft. from the shaft, with 20 ft. to go to reach a point beneath the rich shoot worked on the 200-ft. level. The 'mud-fault' has been reached, and important developments are anticipated.

Manhattan, June 21.

It is reported that the drift on the 300-ft. level of the Manhattan Consolidated has been extended under the ore-shoot developed on the 200-ft. level, and has broken into high-grade ore.

#### OREGON

##### JOSEPHINE COUNTY

(Special Correspondence.)—Operations have been resumed on 'The Diamond Creek' cinnabar property, 16 miles south-west of here. This property is owned and operated by W. Ehrman, John Taggart, and L. C. Cole. Preparations are being made to install machinery.

The Preston Peak copper mine is under option to J. F. Reddy of Grants Pass. It is reported that an Eastern company is ready to take over the option and begin operations. This mine is opened to the depth of 1300 ft. There are many thousand tons of ore in sight showing from 3½ to 20% copper and from \$4 to \$8 per ton gold.

A. Justin Townsend, of Lynn, Massachusetts, owner of the Pacific placer mine, is planning to put in a dredge capable of

handling 2000 yards of gravel daily. This will be used in addition to the hydraulic equipment.

The Collard-Moore and Collard chrome mine is one of the largest shippers in this district. The owners have installed a concentrator, and are shipping some high-grade massive chrome ore that requires no concentration.

A body of chrome ore was found 6 miles south-east of Waldo by W. Bunch and son and Walter Smith. It is only a few hundred feet from the Kerby-Holland stage-road, near the old Sly ranch. Ore is being mined and shipped by way of Grants Pass.

The Osgood placer mine, located in Fry gulch, is a dependable gold producer. It is owned by F. H. Osgood, of Seattle, and has been leased by James Logan for the past four years. This property comprises about 640 acres. Three giants are in operation. Water is taken from the east fork of the Illinois river.

Waldo, June 23.

## TEXAS

### LLANO COUNTY

Ceylon E. Lyman, president of the Wakefield Iron & Coal Land Improvement Co., of Minneapolis, Minnesota, says in the *Manufacturers Record*:

We are continuing the development of a large graphite deposit which we were working last year, and it is proving to extend over an area two miles long and embracing several veins, some of which are 50 to 150 ft. wide. Assays from these veins run from 12 to 35% in graphite.

We are not doing anything in manganese at present, owing to the distance from a railroad, although we may do some work to determine the extent of one deposit in view of the possible wants of the Government. In this course we may be influenced by a report recently made by a representative of the Government, who pronounced it a large and remarkable deposit.

## CANADA

### YUKON TERRITORY

It is reported from Dawson that when transportation on the Yukon opens, \$9,000,000 in gold will be shipped out from the Yukon Basin districts as the result of the season's clean-up. Most of this is from gravel mined during the winter months and washed during the early summer when water was available.

## MEXICO

### VERA CRUZ

(Special Correspondence.)—According to advices received here from Teziutlan, State of Vera Cruz, the large smelter of the Compañía Metalúrgica at that place is now in full operation. This company has been operating large copper mines in that district for many years and its output of metal was large before the revolutionary period. The conditions of banditry interfered with railroad transportation to and from the company's property, but these conditions in that particular locality are said to have shown improvement of late. There has been a project on foot for a long time to construct a railroad from Teziutlan to the prospective deep-water port of Nautla, situated about midway between Vera Cruz and Tuxpam, and the Federal Government has signified its intention of carrying out this work at the earliest possible moment. Connected with the construction of the railroad will be the building of extensive harbor and port works at Nautla, at an estimated cost of about \$2,000,000.

Monterrey, June 23.

A recent report from Cananea states that everything there is quiet at present. The authorities have taken charge of the mines, mills, and smelters of the Greene-Cananea company and has placed guards of soldiers at all the properties. It is also reported that the authorities contemplate starting up the mines and works, but nothing definite is yet known concerning this.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

RUSH M. HESS is at Bouse, Arizona.

WILLIAM TRUVAN is in Plumas county.

C. EBB WUENSCH is in Calaveras county, California.

E. A. S. WHITTARD was in San Francisco from Tuolumne.

P. T. McGRATH is in San Francisco from Phoenix, Arizona.

AUGUSTUS LOCKE, of Boston, is visiting California mining districts.

FREDERICK LAIST has returned to Anaconda from South America.

WALDEMAR LINDGREN has returned to Boston from South America.

CHARLES JANIN, on his return from Russia, has gone to Washington.

H. R. PLATE, of New York, is at the Sheep Ranch mine, in Calaveras county.

ANDREW C. LAWSON has completed an examination of the coalfields of northern Arizona.

FRANK H. PROBERT has been making a geologic examination of the Rochester mines in Nevada.

S. F. SHAW is re-opening the Panaco mine, in Coahuila, Mexico, for the A. S. & R. Company.

L. P. PRESSLER has returned from Mexico and is now with the Tonopah Mining Company at Tonopah, Nevada.

D'ARCY WEATHEREE and ROSS B. HOFMANN sailed by the 'Tenyo Maru' for China and Siberia on June 30.

SUMNER S. SMITH has been named resident engineer for the Alaskan Engineering Commission at Anchorage.

G. H. WOLHAUTER has left the Magma mill of the Utah Copper Co. to join the Michigan College of Mines Battalion.

WILL D. COGHILL has been appointed metallurgist at the Seattle experiment station of the U. S. Bureau of Mines.

H. J. WENDLER has been at Mokelumne Hill from Sonora, Mexico, making an examination of the Mokelumne group of mines.

E. S. BOALICH has returned from Washington, and has taken the position as mining engineer with the California State Mining Bureau.

J. S. DILLER will make San Francisco his headquarters for about three weeks while studying chrome deposits for the U. S. Geological Survey.

CHARLES S. GALBRAITH has resigned from his connection with the Callow flotation business and has opened an office at Webb City, Missouri, as a metallurgical and civil engineer.

HOWLAND BANCROFT, having finished examinations in Colorado, Wyoming, and New Mexico, has gone to New York, where he will be at the Engineer's Club until the middle of July.

DOUGLAS A. MUTCH, manager for the Hudson Bay Mines, Ltd., at Cobalt, Ontario, has been appointed consulting engineer for the Dome Lake Mining & Milling Co., at South Porcupine.

FRANK R. CORWIN has resigned his position as assistant superintendent of the International smelter to take charge of the Consolidated Arizona Smelter Co.'s smelter at Humboldt, Arizona, in the capacity of superintendent.

A. M. SWARTLEY is acting as director of the Oregon Bureau of Mines and Geology during the absence of HENRY M. PARKS, who is a captain of engineers in the Officers Reserve Corps, and is now at Vancouver Barracks, Washington.

ALFRED H. BROOKS, formerly in charge of the Division of Alaskan Mineral Resources of the U. S. Geological Survey, has been appointed a captain in the Engineer Officers Reserve Corps and ordered to report for training. During Mr. Brooks' absence on military duty, Mr. George C. Martin will be geologist, acting in charge of Alaskan work.

# THE METAL MARKET

## METAL PRICES

San Francisco, July 3.

Antimony, cents per pound.....	18.50—22.00
Electrolytic copper, cents per pound.....	34.50
Pig lead, cents per pound.....	12.25—12.50
Platinum, soft and hard metal, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	\$85
Spelter, cents per pound.....	11.50
Tin, cents per pound.....	59
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, July 3.

Aluminum-dust (100-lb. lots), per lb.....	\$1.00
Aluminum-dust (ton lots), per lb.....	\$0.95
Antimony, 50% metal, per unit.....	\$1.35
Chrome, 40% and over, f.o.b. cars California, cents per unit.....	50—55
Magnetite, crude, per ton.....	\$8.00—12.00
Tin, cents per pound.....	60
Tungsten, 60% WO <sub>3</sub> , per unit.....	\$25.00—30.00
Molybdenite, per unit for MoS <sub>2</sub> , contained.....	40.00
Manganese, 45% (under 35% metal not desired), cents, unit.....	33—37

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburgh, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese.....	Per unit \$1.00
48 to 49% metallic manganese.....	0.98
43 to 48% metallic manganese.....	0.95
40 to 43% metallic manganese.....	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F. the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

Tungsten has taken a sharp advance, owing to continued and increasing demand, and scarcity of the supply to meet it. From a nominal price of \$20 to \$22 per unit for 60% ore, the price has risen to \$25 to \$30 per unit, and unless indications are misleading it will go still higher. Some ore of low grade has been shipped from the mines at Atolia to Boulder county, Colorado, for concentration.

## EASTERN METAL MARKET

(By wire from New York)

July 3.—Copper dull and nominal at 32.25c. Lead is quiet at 11.70 to 11.50c. Zinc is dead and lower at 9.37 to 9.25c. Platinum shows no change, being \$105 for soft and \$111 for hard metal. The average price of tin in the month of June was 61.93c. per pound.

## COPPER

High-record levels have been reached by silver sales at 80% c. per oz. at Vancouver. This new top price indicating a premium of about 2c. per oz. over the New York quotation, was made by Nipissing Mines Co. for shipment to the Far East. Producers talk of even higher prices for this metal, basing their contention on the big demand both at home and abroad and the fact that production shows no material increase. Curtailment of operations at Butte, Cananea, and other mining centres where silver figures prominently as a by-product, will cut down the yield of this metal, rather than provide the increase that had been looked for at this time. The Federal Government has been buying silver heavily for some

weeks past, the purchases aggregating 400,000 oz. weekly. The last purchase, however, was for 800,000 ounces.

Much of the silver for the Far East now goes direct from the United States or Canada from Pacific ports rather than through the medium of the London market which necessitates crossing the Atlantic. This is because of the high shipping-costs with Atlantic war-risk insurance to London. Until recently it has been next to impossible to break the hold which English brokers have always held upon the Far Eastern markets.

With an advance of 6 1/4 c. from the low point of the year, March 27, silver prices have reached the highest level since 1892. They are now actually higher than at any time during the sensational advance of May 1916, when 7 1/4 c. was twice touched. Every indication points to 80c. silver in the near future.

The Bunker Hill & Sullivan Mining & Concentrating Co., of Kellogg, Idaho, paid dividend No. 254, of \$81,750, on June 4, and a dividend, No. 255, of \$81,750, on July 3. An extra dividend, No. 256, of \$81,750, was also paid July 3. These dividends bring the grand total paid by this company to date to \$1,716,000.

The Hecla Mining Co. of Wallace, Idaho, has declared dividend No. 169 of 15c. per share, being \$150,000. Total for 1917, \$900,000. Total paid to date, \$6,205,000.

It is reported that the leading lead producers of the Coeur d'Alene mines have agreed to sell 2000 tons of lead to the Government at 8c. per pound.

## MOLYBDENUM

Such small quantities as were offered on the New York market changed hands at \$2.10 per pound MoS<sub>2</sub> for 90% concentrate.

## ANTIMONY

The market is very dull and little business has been reported. Nominally, prompt antimony is quoted from 19 to 19 1/4 c., with future quotations ranging from 14 to 16c., according to position. Needle-antimony, however, remains firm at 12c. for spot and 9 to 9 1/4 c. for future delivery.

## MANGANESE

Manganese is unchanged with the schedule price of \$1 per unit for high-grade ore.

# Eastern Metal Market

New York, June 27.

All the metals grow more inactive rather than otherwise as the weeks go by—due to the continued uncertainty regarding Government decisions as to the quantity and price of probable purchases. The net effect is general stagnation.

Copper quotations are practically nominal with actual business of small volume.

Lead is in small demand and lower.

Tin is dull and has declined.

Zinc is dead but a little business has been done on lower prices.

Antimony is inactive and unchanged.

In the steel market a new and serious uncertainty has been injected due to the agitation of Government control of prices, including coal and coke, thus increasing the perplexity of buyers. Pig-iron buyers and purchasers of finished steel are much disturbed over the proposed fixing of maximum prices in private transactions. Government buying continues to grow in volume, coming from various sources. Japanese buyers of ship-plates are grabbing every bit of tonnage they can lay hands on, paying as high as 9.90c. for 1000 tons for early shipment. The whole market continues to advance in the scramble for the small quantity of steel available for early shipment.

## COPPER

All sorts of rumors are emanating from Washington as to the negotiations in reference to copper purchases by this and the other belligerent governments. Estimates of the amount our own army and navy will need for the remainder of 1917 approximates 225,000,000 lb., while others state that these needs for 12 months will exceed 380,000,000 lb. As to price, common talk is that to the Government 25c. will be the settled figure with 28c. per lb. to the Allies. It is even stated that deliveries are now being made in certain urgent cases on Government account at 25c. per lb. Other reports are disquieting and are to the effect that there is a decided controversy regarding the price-question as it relates to the cost of copper production and the whole situation is disquieting. Business has come to a halt and the hesitancy is expected to continue until the problem is cleared up. This is not the only unsettling factor. It is stated that certain large brass interests have been compelled to shut down indefinitely. Consumers will not come into the market under present conditions, and sales have been light. The market is a stale and drifting one. Price quotations are almost distinctly nominal. Early delivery Lake and electrolytic is held at about 32.25c., New York, with third quarter at 30.50c., and last quarter 29c. to 29.50c. Copper exports for May are returned as 45,241 gross tons, bringing the total to June 1 to 225,967 tons. The contrast is revealed by the fact that exports to May 1 this year are 180,726 tons, against only 92,286 tons in the same four months of 1916. The London market is unchanged at £142 for spot and £138 for future electrolytic copper.

## TIN

Announcement has been made of the personnel of the sub-committee on tin of the Council of National Defense as appointed by the American Iron and Steel Institute. It is made up of John Hughes, chairman, assistant to the president, United States Steel Corporation; E. R. Crawford, president, McKeesport Tin Plate Co.; A. B. Hall, manager, metal department National Lead Co.; Theo. Pratt, assistant manager, manufacturing department Standard Oil Co., and John A. Fry, purchasing agent, American Can Co. This committee has been approved and confirmed by the Government but its personnel does not cause satisfaction among importers and dealers, made

up as it is almost entirely of consumers of tin. The market late last week was featureless and characterized by lack of business. Considerable complaint was voiced by dealers and importers. The appearance and offering of Chinese tin was also an unsettling influence. Late in the week sales were made of both Banca and Chinese tin but not in large volume and mostly for future delivery. Early this week more activity was experienced, sales on Monday amounting to 200 to 300 tons, nearly all futures, with a little spot, and mostly by two sellers. On Tuesday about 150 tons of futures was sold, and the arrivals of about 300 tons from London caused the spot market to fall to 62c., New York, a decline of 1½c. per lb. since June 20, when sales were made at 63.75c. Arrivals to June 26 inclusive were 1225 tons, with 3081 tons of Straits tin reported afloat. The London quotation on the 25th, the last cable received, was £243 15s. for spot Straits and £241 for futures.

## LEAD

Many believe that a reaction downward is now due, with a probability of its continuance. At any rate the market is easier and slightly lower, with demand light. This is due to the easing of the situation occasioned by the announcement, reported in this market last week almost exclusively, that the Government had made arrangements to purchase its July requirements of about 8000 tons at 8c. per lb., St. Louis. The quantity was considerably less than anticipated, and as a result some producers and dealers, who had been holding stocks against Government needs, had some lead as a surplus which they at once offered for sale. Lead has changed hands recently at 11.50c., St. Louis, or 11.65c. to 11.75c., New York, but at present the market is quiet and has come to a halt. Some dealers held out for 12c. but were left out of the running. The London lead market is £30 10s. for spot and £29 10s. for future delivery lead, unchanged for some time.

## ZINC

With production at a record rate but with demand for the metal at a low ebb, it is rather remarkable that the price holds as firmly as it does. Expectation of large Government needs and the firmness of ore prices are the explanation, but in the last few days there has been a slight weakening. Producers, large and small, are getting weary of their 'watchful waiting' attitude as to the Government's needs and the prices it will pay. Actual buying is not large and there is talk of attempts to find other fields for zinc as substitutes for other metals in which the Germans are said to have achieved marked success. Future deliveries continue to command higher prices than nearby deliveries, but there is more tendency to shade the earlier positions than the other. Quotations for early delivery range around 9.25c., St. Louis, with the forward position held at 9.50c., St. Louis. Sales have been made of fair tonnages for early delivery at a shade under 9.25c., St. Louis, or at 9.12½c., St. Louis, and 9.37½c., New York, while for the future position 9.50c., St. Louis, or 9.75c., New York, has been done with resistance on the part of sellers to shade this. Reports are coming from Washington of extended controversies as to the amount and price of the high-grade and other kinds of zinc soon to be needed by the Government, but nothing definite is forthcoming. By a week from now a clearer outlook is hoped for.

## ANTIMONY

The market continues dull and uninteresting, with demand very light. It is reported that Cookson's antimony is being offered for shipment from England at about 22c., New York, duty paid. Chinese and Japanese grades are practically unchanged at 19c. to 19.50c., New York, duty paid, for early delivery. Futures are in more demand than early deliveries.

# INDUSTRIAL PROGRESS

## Hydraulic Pressure Tests of Oxy-Acetylene Welded and Screwed Pipe Connections

\*The interest created by an article that appeared about a year ago giving a report of tests of oxy-acetylene welded pipe connections and screwed pipe connections tested under tension and compression, and the desire of readers for further informa-

FIG. 1

tion regarding the relative strength of welded and screwed pipe connections, encouraged the experimenters to carry on a second series of tests.

These tests were conducted in the machine-construction laboratory of the University of Kansas and had for their purpose the determination of the relative strength of welded and screwed connections in steel pipe of various sizes when subjected to internal hydraulic pressure.

The pipe samples, which were cut from standard black steel pipe, were from the same stock and hence probably of uniform quality. The welded specimens were made by operators of the Oxweld Acetylene Co., Chicago. The screwed connections were made up with malleable-iron couplings and tees by expert pipe fitters. The pieces for the butt welds were cut at an angle of about 60° in a pipe-cutting machine to get the necessary 'V' groove for welding. The 'T' welds were made by cutting a hole in the run and butting the outlet against the run. The ends of all the specimens were sealed by welding in plugs or discs made from boiler plate punchings. Two of these discs are shown at the bottom of Fig. 3.

\*F. H. Sibley, Professor of Mechanical Engineering, University of Kansas, assisted by Messrs. Maris, Ruth, Schooley, Jespersen, and Dryden.

The specimens were subjected to pressure by means of a small hydraulic pressure pump, Fig. 1, which was made especially for this work. The specimen under test was placed about 25 ft. from the pump and connected to it by means of a 1-in. copper tube. A pressure-gage with a check-valve opening toward the gage was placed between the pump and the specimen. The check-valve was necessary to steady the pressure in order that satisfactory readings could be obtained because some of the samples carried pressures greater than 5000 lb. per sq. in. before failing. The illustrations show several of the specimens tested and their modes of failure.

Welded 2 and 3-in. specimens are shown in Fig. 2. These

failed by splitting along the longitudinal seams of the pipe, the split stopping at the welded section. The 4-in. welded specimens in Fig. 3 bulged under the high pressure but did not fail in either the weld or the pipe-seam.

The mode of failure of two of the screwed connections are shown in Fig. 4. The bursting pressures for the screwed

connections were far below that of the welded specimens and all failed in the fitting. Great difficulty was experienced in testing the specimens made up with screwed fittings because sand-holes developed and the water leaked through the castings to such an extent that it was almost impossible to reach the point of rupture. Fig. 5 shows one of the screwed 'T' specimens under test and illustrates clearly the leaky condition just mentioned.

Examination of the data given in the table shows that in only one case was there failure in the weld and that was merely a leak which did not develop until 3850 lb. per sq. in. pressure was applied. This brings out the point that while leaks are much less likely to occur in welded than in screwed connections they are the principal cause of difficulty. Therefore, pipe-lines that are to be subjected to high pressure, if properly tested for leaks when installed, should give no trouble under service.

The results of these tests bear out the conclusions given in the previous series, namely:

a. The strength of a welded pipe connection is practically the same as that of unwelded pipe. By building up the weld slightly it can be made stronger than the rest of the pipe.

b. The strength of the welded pipe connection is very much greater than that of the malleable-iron screwed fittings.

c. Although a careless or inexperienced operator might produce a leaky joint, nevertheless, if the pipe-line is tested for leaks when installed it should give no difficulty in service.

### Saves \$19,000 Annually Hauling Manganese Ore

Fifty years ago manganese ore was in such demand that the owners of the Ladd mine, a manganese property in San Joaquin county, California, found it profitable to transport it on mule-back to Stockton, a distance of 32 miles. It was then loaded on river boats and carried 90 miles to San Francisco.

larly sought by glass-works on account of the low percentage of iron it contains. It lies in a formation of sandstone, chert, and serpentine. Jasper lies on the hanging wall, sandstone on the foot-wall. There are three adits tapping the vein at a depth of 300 ft. The pay-streak is from 1 to 6 ft. wide, averaging 3 ft. The ore runs from 43 to 55%. A few months after the beginning of the War the price of manganese went up, and M. C. Seagrave, of San Francisco, realizing that the Ladd mine was a 'War Bride' worth cultivating, purchased the property and reopened the mine.

Mr. Seagrave invested \$2750 in transportation-equipment, purchasing eight mules at \$225 each, two 3-ton bottom-dump wagons at \$250 each, and six sets of double-harness at \$75 each. Operating records show that the two mule-teams could make three trips daily and haul 18 tons from the mine of the crushing-plant situated in Corral Hollow on a switch of the Western Pacific railroad, a distance of three miles. The cost of this hauling, including the wages of two drivers and one stable-man, feed for the animals, repairing, shoeing, depreciation, interest on investment, taxes, and insurance, totalled \$17.07 per day. This was an expense of 32c. per ton-mile of ore hauled, 95c. per ton of ore, or \$6.95 cost per trip.

The road over which the mules hauled their loads is black adobe. From the upper ore-chute at the mine there is a 20% grade to the main road, which then skirts the mountain, twisting and turning down a 10% grade for one and a half miles. Here a broad wash is reached. It is the natural drainage of the surrounding mountains. In the summer the road is dusty, full of chuck-holes, and deep adobe ruts, baked to the hardness of cement by the burning rays of the sun.

In the winter the ore-wagons would often sink axle-deep in the black quagmire, and these conditions usually forced the abandonment of all activities during wet weather. For weeks after a heavy rain four mules could barely haul one ton of ore over these roads. Two big mule-teams could not haul enough ore to keep the crusher busy.

Eastern steel-mills began demanding regular tonnage and later went so far as to offer attractive premiums to miners who could meet their requirements. Mr. Seagrave was unable to fill his contracts. He summoned a mining expert, who,

THE LADD MANGANESE MINE, SAN JOAQUIN COUNTY, CALIFORNIA

At this point it was placed aboard sailing ships for a 15,000 mile journey to England, via Cape Horn. As new deposits of this ore were discovered in more accessible places the Ladd mine could not meet the prices of its competitors and the property was closed down.

Manganese ore, such as is found in the Ladd mine, is used for making ferro-manganese steel, and the oxide is particu-

larly after a careful analysis of conditions, recommended the purchase of a White Good Roads Truck and a 5-ton trailer to supplant the mules and 3-ton wagons.

The new motor-equipment cost the mine-owner \$7825, almost three times the original outlay for the mules. But the truck and trailer were able to haul every nine hours a total of 80 tons of ore to the crusher and 80 tons of gravel for repairing

the road. This equipment reduced the cost to 4c. per ton-mile, 12.3c. per ton of ore, or \$2.47 per trip. The truck made eight trips per day, registering 48 miles. The total cost for operating the truck and trailer, including salaries of driver and helper, distillate, oil, grease, depreciation, interest, taxes, insurance, maintenance and repairs on truck, and maintenance, repairs, and tires for the trailer, amounted to \$19.77 per day.

For 300 working days the motor equipment saved the owner \$66.40 per day or a total of \$19,671.05 per year, over the cost of performing the same work with the old facilities.

When the truck and trailer were delivered at the mine the

with offices at 565 West Washington Blvd., Chicago. The new company is composed of five former officers and employees of the Snyder Electric Furnace Company.

### The Absorption Method of Extracting Gasoline From Mineral Oils

The annual report of the State Oil and Gas Supervisor for California contains a description of the absorption method by B. E. Lindsly, engineer for the Honolulu Consolidated Oil Co. The method consists of subjecting gas to intimate contact

LOADING CHUTE FOR LADD MANGANESE MINE

rainy season was but 30 days off, and it required quick work on the part of the owner to place the roads in condition before the wet weather set in. Every ton of ore mined and not delivered to the crusher meant a loss of \$25. To stop hauling ore and repair the road with the mule equipment was not practicable. Building a road by ordinary means would have made necessary the hiring of additional men, wagons, and mules.

The mule-teams were taken off the job, a gravel-elevator was erected in the creek-bed near the ore-crusher, and the truck began its work of hauling both ore and gravel. The ore was loaded at the chute, transported to the crusher, and dumped in less than 30 seconds. The truck was then driven to the gravel-elevator where it was loaded with 10 tons of gravel, and on the return trip to the mine spread it along the road where it was required. The broad steel wheels of the truck rolled the surface hard and smooth.

The truck and trailer with one driver and one helper completed the road and delivered all the ore that was mined to the crusher without interruption, in 26 days. Dangerous curves were straightened out, culverts were built, the road widened in many places, turnouts made, and in many other ways it was improved.

When the road was nearly completed the truck and trailer delivered 10 tons of ore three miles, picked up 10 tons of gravel on the return trip, spread and rolled it, and returned to the chute at the mine in one hour and ten minutes. On the completed road a four-mule team was able to deliver but three tons of ore to the crusher and return empty to the chute in three hours.

The BOOTH-HALL Co. has been formed to conduct an electric-furnace building, engineering, and metallurgical business,

with oil that is completely devoid of gasoline. The gasoline vapors in the gas are deposited in the oil and subsequently recovered by distillation. The gravity of the oil should be about 34° Baumé, and the boiling point sufficiently high to permit an easy separation from the absorbed gasoline.

The cycle of the absorbing-oil is as follows. The oil enters the heat-exchanger, where it transmits heat to the incoming oil. Then it passes to a cooler, to a horizontal absorber, and to a vertical spray-absorber. The gas-pressure forces it to a separator where the pressure is released. The excess gas given off in the separator is collected. This oil passes to the exchanger and to the still, where the gas is extracted and the cycle is repeated.

It is claimed that the absorption method has the following advantages over the compressor method: greater recovery, lower first cost, and lower operating-cost. A recovery of at least 0.1 gal. per 1000 ft. of gas can usually be obtained from even so-called 'dry' gas, or gas that has already been treated by the compressor method. Engineers connected with the U. S. Bureau of Mines have estimated that the first cost of an absorption plant with a capacity of 60,000,000 cu. ft. of gas per day would be \$1 to \$1.50 per 1000 cu. ft. capacity. Doubling this maximum estimate for a small plant, the cost of a 2,000,000 cu. ft. plant would be only \$6000. The output of such a plant, assuming a recovery of 0.25 gal. per 1000 cu. ft. would be 500 gal. of gasoline per day. The cost for labor would not be over \$15 per day. Since the method is patented and controlled by the Hope Natural Gas Co. of Pittsburgh, Pennsylvania, there would also be a royalty charge.

The gravity of the gasoline recovered is usually higher than the commercial product, and therefore requires blending with a lower grade refinery-naphtha to fit it for the retail market.

## START RIGHT

### THE SHERIDAN Shaking GRIZZLY

Will feed and screen  
run of mine ore.

Having the maximum capacity  
and  
consuming the minimum  
horsepower.

It is the ideal feeder for  
YOUR CRUSHER.

Successfully installed in some of the  
largest mills in the West.

## What's the most inexpensive way to effectively protect mine-timbers?

### THE Cement-Gun

Just *Gunite* them. Effectually protect timbering or  
any other wood or metal surfaces with the *Cement-Gun*.

You can line drift where rock slacks  
off; line shafts; repair concrete  
work; waterproof flumes, tunnels,  
or ditches; waterproof dams and  
retaining walls; seal water-bearing  
fissures; or build fire-bulkheads.

The CEMENT-GUN is light and  
easily portable. Its first cost is low  
and its operating cost lower still.  
Any man can use it.

For protective work, compared to  
paint or concrete, GUNITE, the  
cement-sand product, is almost un-  
believably inexpensive. There are  
no forms to build, no costly mixer  
to run, as in the case of concrete;

neither does GUNITE have to be  
renewed from year to year as does  
paint.

Whether your tonnage is ten or ten  
thousand, whether you operate  
mine, mill, or smelter; you have  
use for a CEMENT-GUN. The  
present users number among them  
such concerns as the Anaconda  
Copper Company which owns six  
CEMENT-GUNS and which has re-  
cently constructed effective fire-  
bulkheads of GUNITE.

The uses for a CEMENT-GUN are  
so many, its cost is so low, that  
you cannot afford to neglect to get  
further information.

Write us today mentioning the class of protective  
work which, at present, costs you most and which is  
most unsatisfactory. No obligation. Write.

## THE STANDARD BALL MILL

A Grinding Machine of Proven Efficiency and Capacity  
An Economical Mill to Install and Operate

BALL MILLS, the modern crushing device, take the ore from the crusher to desired size in one operation.

A special feature in THE STANDARD BALL MILL is the self-locking corrugated lining, requires no bolts through shell, will wear thinner and longer than those which are bolted in. No special lifting devices required.

Made in all sizes. Following sizes carried in stock for immediate shipment.

5x4, capacity crusher product to 12 mesh, 10 tons per hour; H.P. required 40.

4x3, capacity crusher product to 12 mesh, 3 tons per hour; H.P. required 15.

Laboratory or Sample Mill, either ball or pebble mill, 250 lbs. per charge.

We also carry in stock for immediate shipment Manganese Steel Balls in sizes 1" to 4" and High Carbon Steel Forged Balls.

**The Morse Bros. Machinery & Supply Co.**  
Denver, Colorado

## Make Your Cement Gravels Pay

### Price Cement Gravel Mill

Has proved itself to be an efficient and most economical means of releasing gold and black sands from cemented gravel, clay, talc or other auriferous material.

The above 6-ft. mill has a capacity of 200 to 450 tons per 24 hrs. and requires only 15 to 20 hp. to operate.

The **Price Jr. Mill** has a capacity of 25 tons per 24 hrs. and requires 3 to 5 hp.

Write for Booklet. Let us quote you.

AWARDED

**American Steel & Wire Company's**  
Trenton-Bleichert System

## Aerial Tramways

NO matter what the contour of the ground, we will construct a tramway that will transfer material at minimum expense; and no grades are too steep to surmount; no rivers or valleys too wide to cross; and no grading, bridges or viaducts of any kind are required. There is practically no limit to the length of these tramways.

Send for complete descriptive catalogue of tramways in use.

### METALLURGY OF THE COMMON METALS

By L. S. AUSTIN

Fourth Edition, Revised. 532 pages. Illustrated. Indexed.  
\$4 Postpaid.

A simple, comprehensive treatise on the metallurgy of gold, silver, copper, iron, lead, and zinc. An ideal book for one who desires to acquire a general knowledge of smelting operations. Published and for sale by

**MINING and Scientific PRESS**  
420 MARKET ST., SAN FRANCISCO

## CORROSIRON

MADE IN CALIFORNIA

has many applications to mining and metallurgical conditions where acid or alkaline solutions have to be employed.

This is an ordinary type of flanged cast pipe. The flanges are faced clear across and are made to conform to standard pipe sizes

A steel pipe fits over a CORROSIRON liner and is peined against the flanges of the CORROSIRON to hold it in place. The space between is filled with non-corrosive material such as plaster of paris or any type of acid cement.

WRITE US CONCERNING YOUR CONDITIONS

## Pacific Foundry Company

SAN FRANCISCO, CALIFORNIA

No. 3 Mill partly assembled.

Made in three sizes: 15 to 30, 30 to 60, and 60 to 120 tons per 24 hours

## PAUCITY OF PARTS in the DENVER QUARTZ MILL means

# LESS

BREAK-DOWNS  
SHUT-DOWNS  
TROUBLE  
EXPENSE  
REPAIRS

because it is a self-contained mill in which all "ginger-bread" work has been eliminated.

Get this. In the DENVER QUARTZ MILL Nothing Breaks Except Rock.

Ask for literature.

**The Denver Quartz Mill & Crusher Co.**  
216-217 Colorado Bldg., Denver, Colo., U. S. A.

## Investigate This

A CYANIDE PROCESS that is *almost automatic*, that will treat ores heretofore unadaptable to cyanide; that will increase the extraction of gold and silver content by from 5 to 15 per cent as employed by mills using Pachuca tanks, air or mechanically agitated pulp with filter presses; that will require one-fourth the labor to operate; that has an initial cost of a fraction of that of the older processes; that will mean increased dividends for your company.

## This Process Is Not An Experiment

It is being successfully employed in milling operations, which attest to all of our claims for its superiority over what has been accepted in the past as standard practice.

One unit consisting of a drum 15 ft. long and 6 ft. in diameter will agitate, filter and wash from 30 to 50 tons of ore a day.

WRITE for details. Our Metallurgical Staff will tell you what this Process can do in your particular case.

## Koering Cyaniding Process Co.

511 HAMMOND BUILDING  
DETROIT, MICH.

## I'm a Salesman

I carry prices, blueprints, photographs, and all the information regarding my line in a **LOOSE-IP-LEAF** Price Book — a handsome, compact loose leaf binder that fits my pocket and is always available.

There is no dead matter in this book because when prices change it is easy to remove the dead sheets and put in fresh ones.

I can arrange the leaves to suit my convenience, and the index enables me to find what I want instantly. I can get fresh sheets anywhere in the country and **LOOSE-IP-LEAF** sheets ALWAYS fit.

Many of my customers have found ring books efficient for pay-roll records, stock books, inventory, reports, sales, claim records, bills payable, trial balance, and many other uses. They get **LOOSE-IP-LEAF** stock forms from their stationers to fit the binders—and avoid made-to-order prices.

Get **LOOSE-IP-LEAF** Books and Forms at any Stationer

**NOTE** **LOOSE-IP-LEAF** Books and Forms Are Acknowledged the Best by both Dealers and Users.

## Everything in Mine Safety

It is a pleasure to announce that, in spite of the German threat of ruthless submarine warfare, the S. S. "Norwegian" brought in a large consignment of the FLEUSS-PROTO SELF-CONTAINED OXYGEN BREATHING APPARATUS and that other consignments are to follow shortly.

In view of the fact that owing to abnormal conditions an advance in price will have to be made in the near future, I would recommend that all users and prospective users of the FLEUSS-PROTO equipment take advantage of the present prices, by anticipating their requirements for the coming year and place their orders promptly.

The new J & B STRETCHER has taken the field east. It covers all requirements, and while substantially made, is much lighter and less expensive than the present high priced ones on the market. The J & B was invented by Mr. W. H. Britton, well known, as being for eighteen years Safety Engineer for one of the largest companies in the East, and Mr. H. L. Johnson, General Superintendent of the same company. Send me postal for prices and full particulars.

Orders for my E. K. K. Sanitary Closet are coming in about as fast as I can take care of them. All will be filled in the order received.

## Everything in Acetylene

At last our HEAVY STEEL "ITP" (IT'S TROUBLE PROOF) FLAT OPEN FLAME CARBIDE LAMP is on the market. It is made according to recommendation of one of the best known mining engineers in the West and is pronounced to be unequalled by any large lamp manufactured. Invented, Made and Sold by Americans. One well known Mine Manager writes me "You have every other Carbide Lamp knocked off the board."

Height of lamp, 6 1/2 in.; to top of bail, 9 in. Weight 24 oz. Burns from 4 1/2 to 9 hours, according to size of burner. Price \$4.00 each.

SPECIAL PRICES IN QUANTITY.

I sell Carbide, Cyanide, and Caustic Soda

**E. D. BULLARD**

268 Market Street

San Francisco, Cal.

## ADAMANT NEW TUBE MILL LINING SILICA

A stone so hard and close grained it cannot be ground on an emery wheel, and yet so tough that it can be worn down in your mill to a thin shell without fracturing.

Equal in every respect to imported linings which are now unobtainable. Delivered at a price 15% to 30% less than the imported product.

### CHEMICAL ANALYSIS

Silica .....	94.0%
Silicate of alumina and potash .....	2.4%
Hydrous silicate of lime .....	2.0%
Oxide of iron .....	1.6%
Crushing strength, pounds per square inch .....	45,300
Abrasion by standard rattler test .....	4.6%
Toughness by coefficient .....	21.5%

Standard cut blocks ready for immediate shipment on receipt of your order. Special blocks cut to your specifications, delivered within a reasonable time.

Send for Sample and Prices.

St. Louis, Mo.

# Men Wanted for Government Service

The following call for skilled men has been received from the Government:

## I. Steel Inspectors (Chief)

**Salary**—Up to \$2,400 per year.

**Duties**—Men will be engaged at the mills, most of which are located in the Pittsburgh district, and will pass on Government steel as it is turned out at the rolling mills.

**Qualifications**—Two years' or more experience in inspection of steel, or in practical metallurgical work. Men having a good education in chemical engineering or metallurgy, plus the above experience, are especially desirable. Preference will be given to men who have had experience in inspection or manufacture of munition steel.

## II. Steel Inspectors (Sub)

**Salary**—\$3.50 to \$5.00 per day.

**Duties**—Same as for (I).

**Qualifications**—Same as for (I).

**NOTE.**—Men now employed by the Government or by firms or corporations engaged in carrying out contracts for the Government or its Allies will not be accepted for these positions unless they can get the written assent of the head of the office, firm or corporation under which the applicant is employed.

**For further information apply California Alumni Association  
114 California Hall, Berkeley, Cal.**

# THE WAUGH "DREADNAUGHT" DRILL STAYS ON THE JOB

Thomas J. Quinn, the Ouray correspondent for The News, in reference to the work in the great Camp Bird tunnel, has this to say:

"After trying four other different kinds of machine drills, the new year finds the Waugh 'Dreadnaught' once more putting in the rounds that enables the Camp Bird 'heading' to be pulled out at the rate of sixteen feet in the twenty-four hours. This is crowding the record pretty close for the kind of ground the 'heading' is now in—andesite-breccia. — *The Rocky Mountain News*.

"Dreadnaughts" used unmounted as hand drills for enlarging a "raise," in the Dome Mines, South Porcupine, Ontario. The ground was a mixture of white quartz and schist, yet with 5 machines they averaged thirty-four 10-ft. holes a shift.

When the steel is binding or runs into a slip, the hole is not lost if you are using a "Dreadnaught," for it can be cranked back while running with the full force of rotation, without danger of breakage. In a number of mines where "Dreadnaughts" are being used with drills of other makes, they use their "Dreadnaughts" for pulling steels that have been stuck by other machines.

# Graphical Solution of Fault Problems

By C. F. TOLMAN, Jr.

Professor of Geology and Mining Engineering, The  
School of Mines, University of Arizona, and  
State Geologist of Arizona.

43 Pages 23 Figures 5 x 8 in., Limp Leather

\$1.00 Postpaid

The presentation of the subject is in as simple a form as possible. One who can read mine maps and has a fair geometrical sense regarding underground geological features can understand and apply these principles without necessarily having had previous training in descriptive geometry and graphical work.

**MINE SAMPLING  
AND VALUING**

By C. S. HERZIG

with a chapter on

**SAMPLING PLACER DEPOSITS**

by CHESTER WELLS PURINGTON

163 Pages      6x9      Illustrated      Cloth \$2 Postpaid

This is the first comprehensive treatise on a most important part of the mining engineer's work. It presents a complete logical and well-rounded discussion of the principles and practice of sampling and valuing mines. Most experienced engineers will be glad to have such a volume in their library, and to the young engineer, who has not been through the mill, it should prove well nigh invaluable.

# THE OPPORTUNITY PAGE

## OPPORTUNITIES

Under this heading announcements may be made of new and second-hand machinery or supplies, for sale or wanted. The cost is five cents per word, one dollar minimum order. Remittances MUST accompany order. Copy must be received by Saturday morning for the following week's issue.

**FOR SALE**—Two quintuplex pumps, lead lined, capacity 1000 gallons per minute against 500-foot head, each connected to a 200 H.P. Westinghouse two-speed motor. These pumps are in fine condition, having run for only a few weeks in the Ward shaft of the Comstock Lode. Address Opp. 629, Mining and Scientific Press. LT 7-21

**AIR COMPRESSOR FOR SALE**—Ingersoll-Sargeant Duplex steam-driven compound, class "HC". Steam cyl. 14x14 in., air cyl. 22½x14½ in. with 14-in. stroke. Good condition. Address Tonopah Midway Consolidated Mining Co., Tonopah, Nev. TF

**WANTED**—Good second-hand assay outfit including scales. Address Box 88, Mina, Nevada. LT 7-7

**FOR SALE, CHEAP**—Twenty stamps, weight 1000 pounds each. Cost new \$877. Iron work complete for two Joshua Hendy 10-stamp batteries. Also 2700 feet of ¾-inch wire rope at 15c. per foot and 7000 feet ¾-inch wire rope at 10c. per foot. Original Amador Consolidated Mines Co., Amador City, California. LT 7-14

**GURLEY ENGINEER'S TRANSIT** with complete arc, stadia, wires, etc., reading to thirty seconds; will sell for \$200. Can be seen at Mining and Scientific Press office. Address Opp. 598, Mining and Scientific press. LT 7-7

**WANTED**—1000 tons manganese ore; reply to Manganese Company of California, 180 Sutter street, San Francisco. TF

## PORTLAND FILTERS—NEW

Two 12 ft. by 10 ft. at a sacrifice.  
These have never been set up. Now in Denver.

- 1—¾ H.P. General Electric, 1900 R.P.M.
- 1—3 H.P. General Electric, 1820 R.P.M.

### ALTERNATING CURRENT MOTORS

- 3 Phase, 60 Cycle
- 1—3 H.P. Westinghouse, 220/440 Volt, 1700 R.P.M.
- 2—3 H.P. General Electric, 220/440 Volt, 1800 R.P.M.
- 1—5 H.P. General Electric, 220/440 Volt, 1800 R.P.M.
- 1—10 H.P. General Electric, 220/440 Volt, 1800 R.P.M.
- 2—10 H.P. General Electric, 220/440 Volt, 1200 R.P.M.
- 2—30 H.P. Westinghouse, 220/440 Volt, 825 R.P.M.
- 1—40 H.P. General Electric, 220/440 Volt, 900 R.P.M.
- 1—100 H.P. General Electric, 220/440 Volt, 600 R.P.M.
- 1—120 H.P. General Electric, Synchronous, 440 Volt, 300 R.P.M.

### ELECTRIC LOCOMOTIVES

- 2—10 Ton Baldwin-Westinghouse, Standard Gauge, 250 Volt.
- 2—7 Ton Jeffery, 30" Gauge, 250 Volt.
- 1—5 Ton General Electric, 24 Gauge, 250 Volt.
- 2—3 Ton Jeffery, 24" Gauge, 250 Volt.

### STEAM LOCOMOTIVES

- 1—50 Ton Shay, 38" Gauge.
- 3—50 Ton Baldwin, Standard Gauge.

### STEAM DRIVEN COMPRESSORS

- 1—8x9x12 Leyner.
- 1—10x10x10 Smith-Vaile.
- 1—12 x 13½ x 8½ x 16 Leyner Compound.
- 1—10x16x9x14 Rand Imperial Compound.
- 2—14x14x22 Rand, Class C.
- 1—14½x16x10x17 Leyner Compound.
- 1—14 x 16 x 9½ x 16 Norwalk Compound.
- 1—11½x20½x18x11x22 Leyner Compound.
- 1—16x18x11x22 Leyner Compound.
- 1—18 x 20 x 13½ x 20 Norwalk Compound.

### BELT DRIVEN COMPRESSORS

- 1—8x8 Bury, Single.
- 1—11½x8½x14 Leyner Compound.
- 1—14½x9½x8 Ingersoll-Rand Compound.
- 1—24½ x 14½ x 14 Ingersoll-Rand Compound.

### BLOWERS

- 1—85 cu. ft. Fiqua Positive Blower.
- 1—24 cu. ft. Connersville Positive Blower.
- 1—No. 5 Root Positive Blower.
- 5—No. 5 Baker Positive Blowers.
- 1—No. 3 Garden City Positive Blower.
- 1—No. 2 Garden City Positive Blower.
- 1—No. 10 Sturtevant Monogram Blower.
- 1—No. 6 Sturtevant Pressure Blower.
- 1—No. 1 Buffalo Pressure Blower.

### EXHAUSTERS

- 4—108" Garden City, Double Steel Plate Exhausters, for hot blast.
- 1—8" Steel Plate Mine Fan, Engine driven.
- 2—90" Sturtevant Steel Plate Exhausters.
- 1—72" American Steel Plate Exhauster.
- 6—60" Sturtevant Steel Plate Exhausters.
- 3—No. 7 Sturtevant Monogram Exhausters.
- 1—No. 7 Buffalo Volume Exhauster.

Mining and Scientific Press

## POSITIONS WANTED

The cost of advertising for positions wanted is 2 cents per word per insertion. Minimum order 50 cents. Replies forwarded without extra charge. Remittances must accompany order. Copy must be received Saturday morning for the following week's issue.

**MINING ENGINEER** returned from two years successful management of important gold property in South America, now open for engagement. Over 15 years experience, development, construction and operation of mines and mills in Spanish America, Canada and the United States. Address PW 634, Mining and Scientific Press. LT 7-14

**MINE FOREMAN** wishes to make change; long experience; gets results; best references. Address PW 635, Mining and Scientific Press. LT 7-21

**ALL AROUND PRACTICAL MAN** wants position as general foreman of construction, good organizer of men; married, steady, sober, A-1 references; no job too large to handle. Address PA 632, Mining and Scientific Press. LT 7-21

**HOISTING PLANT** with new 6 H.P. gasoline hoist, rope, ore bucket, sheave, shaft and boxes, \$475. Also several steam, electric and belt hoists, water wheels, small milling plant and other machinery. U. S. Iron Works, Seattle, Wash. eow-TF

**GOLD AND SILVER MINES FOR SALE**—Only first-class propositions handled. If interested, address S. T. Schreiber, Boise, Idaho. TF-eow

**ENGINEER AND MECHANIC**, age 32, American, open for position July 15, 1917. Gas engines, Meitz & Weiss and Wordberg oil engines, generators, motors, hoist and millman. Go anywhere. Address PW 633, Mining and Scientific Press. LT 7-14

**ENGINEER WISHES POSITION**; hoisting, stationary or marine; steam or gas. Have had long, varied experience as chief engineer and mine mechanic. All sorts of installations, repairs and adjustments. Solve your gas engine problems and reduce your fuel expense. References and service letters. Address M. A. K., Box 228, Oatman, Arizona. LT 7-14

**MINING ENGINEER**, 13 years experience in mining, cyaniding, concentration and management, age 37, married. Good references. Open for engagement after June 1. Denver interview. Address PW 600, Mining and Scientific Press. LT 7-14

**POSITION WANTED**—Melt-room man and assayer, experienced in smelting cyanide precipitates and refining base bullion. Some experience as millman. Address PW 606, Mining and Scientific Press. LT 7-7

**WANTED**—Position as mill superintendent. Thoroughly experienced; flotation a specialty. Now operating flotation plant successfully; desire change. Best of references present employers. Address PW 614, Mining and Scientific Press. LT 8-4

**THOROUGHLY COMPETENT ASSAYER AND CHEMIST** desires position with smelting works, mill or mine; also surveying, superintendence. Excellent references for skill and good work. Address PW 607, Mining and Scientific Press. LT 7-7

**MINING AND SCIENTIFIC PRESS** wants a permanent circulation representative in every mining community in the world. Replies will be held confidential if desired. Address, The Manager, Mining and Scientific Press.

## EQUIPMENT FOR SALE

We offer for sale the following equipment for immediate delivery, subject to prior sale.

- 6 Standard Callow 8-ft. tanks, complete.
- 2 Type 1-B Callow Duplex Screens, complete with overhead step pulley, steel housings, spray boxes, etc. Equipped with phosphor bronze ton cap belts.
- 8 Butchart Tables, complete with linoleum covers and No. 2 type riffing.

Above equipment in very good condition, used only two months. Prices upon application

Address all communications to  
**UTAH LEASING COMPANY**  
305 Newhouse Bldg., Salt Lake

LT 7-21

## WILFLEY TABLES

- 7—No. 4, perfect condition, complete with new riffles; practically unused. Immediate delivery.
- 2—No. 2, good condition.
- 2—No. 6, with new riffles, steel frame, perfect.

**Southwestern Wrecking Company**  
El Paso, Texas

## POSITIONS AVAILABLE

Announcements in this column are secured through the co-operation of many of the largest mining companies in the United States. Advertisements under this heading will be inserted two times without charge. Additional insertions charged at the rate of 2c. per word.

**SALES ENGINEER WANTED**—Sales engineer of ability and experience with ore-treatment machinery. Fine opportunity for one who can make good. Address PA 628, Mining and Scientific Press. LT 7-14

**MECHANICAL DRAFTSMEN**—Several men required who are experienced on mill and smelter design. Liberal salaries. Business Men's Clearing House, Denver, Colorado. LT 7-14

## TEMPORARY FREE REGISTRATION

While present heavy demand continues for well-qualified men all branches mining, milling, smelting, we will accept, without registration charge, applications from mining or metallurgical engineers, assayers, chemists, etc., who are technical graduates and who would consider salaries of \$125 and lower. Desirable positions secured promptly. We have placed fourteen thousand men in positions, at salaries up to \$6,500.00 per annum. Established 14 years.

Business-Men's Clearing House, Denver, Colorado

## ANTIMONY ORES WANTED

Any grade over 15%. State quantity which can be delivered. State Analysis. Send Samples.

**NICHOLS-LAYNG CHEMICAL CO., INC.**  
KIRKWOOD AVE. AND QUINT ST., SAN FRANCISCO, CAL.

## Structural Steel Head Frame

Two compartment 70' designed for 100 H.P., complete with sheaves and ore bins. One of the most substantial gallows frames in the southwest. K.D. marked for re-erection, exactly the same as new. Send for photos.

**SOUTHWESTERN WRECKING COMPANY**  
EL PASO, TEXAS

## MOTOR TRUCKING

### MOUNTAIN HAULING A SPECIALTY

California, Nevada, Arizona.  
**E. M. MOORES**, 15th and Alabama Streets, SAN FRANCISCO  
Telephone Market 7274

## COMPLETE STAMP MILL

50 stamps, 1050 lbs., Denver Engineering Works, latest type, chrome steel shoes and dies, complete with all timers, feeders, etc. Used three months; perfect condition.

**SOUTHWESTERN WRECKING COMPANY**  
EL PASO, TEXAS

Attorney at Law

Notary Public and Commissioner of Deeds for New York,  
805 Pacific Bldg., Fourth and Market Streets, San Francisco.

## For Lubrication of Mine Machinery

**S**ECURE a lubrication service for your mine equipment that is exceptionally economical and at the same time highly efficient.

*Hoisting Engines  
Compressors  
Winding Machines  
Blower Fans  
Crushers  
Drills  
Motors  
Cars  
Locomotives*

This equipment when lubricated with

## ALBANY GREASE

will produce maximum results, operating with cool, easy running bearings—at a minimum cost. We have collected data in detail giving results of comparative lubrication tests on mine equipment which points out the great saving secured with Albany Grease. This data will be sent you on request. You can conduct a test on Albany Grease at our expense. A sufficient quantity of Albany Grease and an Albany Cup will be sent you without charge, upon receipt of your request.

Your dealer sells Albany Grease. If not, order direct.

### Albany Lubricating Co.

Adam Cook's Sons, Props.

DENVER, COLORADO

LT-7-7

**NEW AND SECOND-HAND MACHINERY**

Before you order your equipment get my prices on new and second-hand boilers, steam and gas engines, pumps and all classes of machinery. Also carry a line of high compression Diesel crude oil engines in small sizes. No spark troubles; just the engine for prospectors.

Give full details when writing

**PAUL H. COOP, 1111 Hobart Bldg., San Francisco**

**CORLISS ENGINE**

We can make immediate delivery on the following engines, which are in good mechanical order:

- 1—100 H.P.
- 1—110 H.P.
- 1—120 H.P.
- 1—150 H.P.

**SOUTHWESTERN WRECKING COMPANY, El Paso, Texas**

**40-H.P. Fairbanks-Morse Gas Hoist**

Single Drum, direct connected, geared, complete with 750 ft. new  $\frac{5}{8}$ " rope; absolutely perfect, immediate delivery.

**Southwestern Wrecking Company**  
El Paso, Texas

**POWER PLANT**  
**For Immediate Delivery**

- 2—350 B.H.P. Wolf Cross Compound Superheated Steam Locomobiles complete, with Condensers, Boiler Feed Pumps, Injectors and Feed Water Heater.
- 2—Dahl Liquid Oil Burning Systems Complete with Pumps and Heaters.
- 2—General Electric A.T.B. 32 pole, 345 K.V.A. 3-60-480 Engine Generators.
- 2—Type B.L.C., 35 K.W.H., 850 R.P.M., 125 V., Belt Driven Exciters.
- 8—Fort Wayne 60 cycle, 219 K.V.A. (175 K.W. 8-10 P.F.), 33,000 volt primary to 480 volt secondary, single phase Transformers.
- 2—Type H, 60 cycle, 25 K.V.A., 33,000 volt primary to 110-220 volt secondary, single phase Transformers.
- 1—Blue Vermont Marble Switchboard, with all necessary instruments.
- 8—3-phase Aluminum Cell Lightning Arresters.
- 6—200 amp. Choke Coils.

Above equipment has been slightly used but not misused and is guaranteed to be in first-class condition. Power plant is for sale only as a whole.

**Mill Equipment**

- 1—32'x10' Gates Revolving Screen.
- 1—6'x16" Hardinge Mill.
- 2—32'x15' Dorr Agitators and Tanks.
- 2—36" Perrin Presses.
- 1—6x9 Aldrich Vertical Triplex Pump.
- 1—42x48 Belt Driven A.C. Tube Mill.
- 1—52" Merrill Precipitating Press, 30 leaves.
- 1—No. 787 H-H-M Steel Bullion Safe.
- 1—42" Carlin Grinding pan.
- 2—Erie City Economy Boilers.
- 1—3x2x4 Duplex Boiler Feed Pump.
- Full Refinery Equipment.
- Lot large Redwood Tanks, good condition.
- Pulleys, Shafting and Transmission Equipment.

**Motors**

- 2—50 H.P. 3-60-440, 720 R.P.M. G.E. Motors.
- 1—40 H.P. 3-60-440, 900 R.P.M. G.E. Motor.
- 2—15 H.P. 3-60-440, 900 R.P.M. G.E. Motors.

All above motors equipped with starting compensators arranged for conduit wiring, no voltage release and overload relays.

**Miscellaneous**

- 1—No. 1174 F.M. 1000-lb. Portable Scale.
  - 1—No. 1128 F.M. Platform Scale.
  - 1—No. 1046 F.M. double beam Warehouse Scale.
  - 1—No. 1928 ten-ton F.M. single-beam Wagon Scale.
  - 1—50-ton F.M. 4'x10' Track Scale with Type R Registering Beam and Steel Frame.
  - 1—7x10 Double Cylinder Steam Hoist.
  - 1—15 H.P. Fairbanks Gasoline Hoist and 500 ft. rope.
  - Complete Boarding House Equipment.
- Power Plant may be inspected at Beowawe, Nev. Other material at Buckhorn, Nev.  
Write for particulars and prices. Above list is incomplete.

The upper illustration shows two 5-in. 3-stage Cameron Pumps, direct connected, to 300 H.P. motor, giving a capacity of 600 G.P.M., against 1,225 feet head at 1,760 R.P.M. These

## Cameron Centrifugals

were run continuously without inspection for several months, and gave their initial high efficiency. After replacing the packing in the stuffing boxes, they have been operated to date without stopping.

This is just another example of the continuous High Efficiency you can be sure of when you install CAMERON CENTRIFUGALS.

As shown by the lower illustration, they are very simple in design, compact and strong, with horizontally split casings, which give ready access to the working parts.

# Marion

*Steam Shovels, Dredges, Draglines  
and Kindred Machinery*

**T**AKING into account its very difficult operating conditions, and the known ability of Marion Equipment to go straight through with whatever it starts, the Canadian Klondyke Mining Company, Ltd., of Dawson, Y. T., some years ago concluded that the best move it could make, when purchasing a Placer Mining Dredge, was to select a "Marion." The wisdom of this decision is today evident in the fact that

**This Marion Dredge Operated Late Into December — 175 Miles From the Arctic Circle**  
—with the air so cold that the Dredge would have frozen up solidly if stopped even a few moments—necessitating a complete shutdown until Spring. The Canadian Klondyke Mining Company, Ltd., is now employing "Marions" exclusively.

Whatever your requirements, you, too, can depend on "Marion." We invite you to forward particulars about your work, as a basis upon which we may submit definite recommendations. There will be no obligation upon you in requesting this information.

**The Marion Steam Shovel Company, Marion, Ohio**

## OIL FINDING An Introduction to the Geological Study of Petroleum

By E. CUNNINGHAM CRAIG, with an introduction by  
SIR BOVERTON REDWOOD

195 pages. Illustrated. Cloth, 5½ x 9, \$2.40 postpaid.

This admirable book, while intended primarily for geologists, and especially for young geologists, is written in a style so free from technicalities that it may be studied with profit by a far wider circle, including all those interested in the petroleum industry either in an administrative capacity or as investors. The book will be especially helpful to those making preliminary examinations of a field.

The chapter headings are: The Origin of Petroleum. Processes of Formation: The Migration, Filtration, and Subterranean Storage of Petroleum; Lateral Variation; Geological Structure; Indications of Petroleum; Stratigraphy; Location of Wells; Field Work; Indoor Work.

*the keynote of success of the*

# LUNKENHEIMER "Clip" Gate Valve

It has but two internal movable parts, viz: the stem and single, sharp tapered double faced disc. The body and bonnet are held together by a steel "Clip," which adds strength and rigidity to the valve and facilitates taking apart for cleaning or repairs.

The joint between the body and bonnet is practically indestructible, it being a seamless copper wire gasket, partially imbedded in the top of the valve body. The stuffing box can easily be repacked while valve is under pressure and wide open.

The body and bonnet are made of Lunkenheim "Valve-iron" with the trimmings of Lunkenheim "Valve-bronze." For handling cyanides, creosote, alkaline solutions, etc., the "Clip" can be furnished in ALL IRON.

Specify Lunkenheim "Clip" and insist on having the genuine.

Your local dealer can furnish them; if not, write us.

Write for Booklet No. 505-CD.

## THE EXAMINATION OF PROSPECTS

By C. GODFREY GUNTHER, E.M.

Author of "Electro-Magnetic Ore Separation."

222 Pages, 79 Illustrations. Leather, Pocket Size.  
\$2.00 Postpaid.

Mr. Gunther's book emphasizes not only the fundamental business aspects of prospecting, but also the applications of economic geology to the examination of prospects.

The first part of the book covers the general considerations—the preliminary phases of the work. The latter deals with deposits—types, distribution, structural features, ores and ore-shoots, etc.

It is a compact practical book.

Carried in Stock by

# THE PORTLAND FILTER

## Continuous and Automatic

A thin cake, quickly formed, thoroughly washed with little solution and water, and easily removed, is the basis of Portland Filter success.

The capacity per unit of filtering area is very great, and the absence of manual labor and attention, economy in power and reduced wear on cloths makes up a cost total which in fairly large installations does not exceed \$0.035 per ton of dry solids.

Patented features place the Portland Filter in a class by itself. Free and unobstructed drainage within the sections results in perfectly uniform suction and drainage over the entire width of face of the machine. Cake is loaded evenly, and is dislodged without clinging more to one part than another.

The Portland is sold outright, and there are absolutely no royalties to pay. It is a completely finished machine, easy to assemble.

Ask for Bulletin 28-B!

Denver, Colo.

ELECTRIC MINE HOISTS OF EXCEPTIONAL QUALITY

## One of the Latest W-S-M Types

The hoists which we build today are splendid tributes to the way in which we are utilizing our 30 years experience by foreseeing the hoisting needs of the mining industry. The hoist shown, for example, is provided with machined herring-bone gears encased in oil-tight housing; steel drums; weighted steel safety brakes, and strong steel clutches, all operated by compressed air cylinders with cataract cylinders attached. The brakes are instantly applied upon failure of air pressure or if electric current is cut off.

Hoist Designed and Built for the Cananea Consolidated Copper Co., Cananea, Mexico

*You can secure continuous operating economy  
by letting us work out your hoisting problems.*

Double Deck Simplex Sand Table

Single Deck Simplex Sand Table

Simplex Rougher and Finisher (Large Size)

## Note:

Our new patented feature on the tables consists of the cleaning or dressing zone being elevated or higher than the riffled portion of the table, but substantially parallel therewith.

This will enable you to make a cleaner concentrate and lower tailing; also treat a much larger tonnage and gives the table an automatic control of the line of separation.

This is the reason *why* the Deister *SIMPLEX* tables are the *best* you can buy today.

Issued Every Saturday

SAN FRANCISCO, JULY 14, 1917

\$4 per Year—15 Cents per Copy

## TABLE OF CONTENTS

### EDITORIAL

	Page
NOTES .....	37
THE STRIKING MINERS .....	38
Labor disturbances in Montana and Arizona; dissatisfied aliens; extravagant ways of living; should the copper companies share their profits with their employees? M. & S. P., July 14, 1917.	

THE NEW METALLURGY .....	39
Early development of hydro-metallurgy coincident with early development of the science of chemistry; mechanical improvements again gave smelting the lead; electro-chemistry now threatening to supersede pyro-metallurgy. M. & S. P., July 14, 1917.	

OPPORTUNITY FOR SMALL ORE-PRODUCERS .....	40
Government's call for lead; shippers to smelters may require one-sixth of the lead to be sold to the Government; recognition of the rights of small producers; miners may force smelters to contract through associations for ore-selling. M. & S. P., July 14, 1917.	

### DISCUSSION

THE DEVELOPMENT OF FLOTATION. By A. Schwarz .....	41
Perspicacity of Dr. Gahl's comments in 1916; finds frothing due to water-soluble substances; reaction between oil and sulphide minerals; reaction between the water-soluble 'frothers' and substances in the pulp forming soaps, thus modifying surface-tension. M. & S. P., July 14, 1917.	

FIRE-PROTECTION IN SHAFTS. By Frank A. Madson .....	41
Two methods of fire-fighting in shafts; fire-plugs at intervals; modification of Grinnell automatic sprinkler system. M. & S. P., July 14, 1917.	

THE EXTRA-LATERAL RIGHT. By Wm. E. Colby and Leroy A. Palmer.....	42
Most of the apex-suits are appealed; such litigation most common where placer-claims are numerous; desirable to sever surface from mineral titles.—Conflicting surface-locations chief cause of litigation; any land-classification based on geologic opinion will provoke litigation; extra-lateral right an anachronism. M. & S. P., July 14, 1917.	

HYDRO-METALLURGY v. SMELTING. By A. E. Drucker .....	44
Prophesies displacement of pyro-metallurgy by wet-methods. M. & S. P., July 14, 1917.	
MISFIRES. By Miner .....	44
M. & S. P., July 14, 1917.	

### ARTICLES

SEALE-SHELLSHEAR 'CASCADE' PROCESS .....	44
Method at Central mine, Broken Hill; reduction of power-cost; no propellers needed. M. & S. P., July 14, 1917.	

### PRINCIPLES OF FLOTATION—II.

By T. A. Rickard .....	45
Bubbles, conditions of formation and stability; thickness of the film; cause of the bubble's lifting power; the substance of the film; selective adsorption of oil on mineral; viscosity in relation to bubble-films; attraction of mineral to the oil-water interface; air does not attach itself to mineral; statement of the flotation hypothesis. M. & S. P., July 14, 1917.	

### WHAT IS A METALLIFEROUS MINERAL?

By L. O. Howard .....	55
Ruling of Commissioner of General Land Office on carnotite ore; classes it with borax, salt, limestone, and potash for purposes of land-classification; bases opinion on fact of radium and uranium being used as salts, and denies that vanadium is a metal. M. & S. P., July 14, 1917.	

### ORURO TIN-SILVER DISTRICT, BOLIVIA.

By Francis Church Lincoln .....	57
Age of the Oruro mines; the tin-silver vein-type; geological setting; order of the ore-minerals. M. & S. P., July 14, 1917.

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.

Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bdg.; New York, 1760 Woolworth Bdg.; London, 724 Salisbury House, E.C.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

Transporting Union Drill over 40 Mile Trail

## These Field Pictures Tell The Story

**The Union Prospecting Drill** is incomparably light and can be transported, handled and operated with an ease heretofore unknown for a drill having its capacity.

The Type B Drill shown in the bottom illustration weighs 2150 lb. Drills of this type are drilling 60 ft. ground and deeper, at the rate of 20 to 25 ft. a day, using 5-in. casing, which cuts a 6 $\frac{3}{8}$  in. diameter hole. The engine burns  $\frac{1}{10}$  of a gal. of gasoline per hour.

Every Drill guaranteed.

# EDITORIAL

T. A. RICKARD, Editor

**I**NDEx for Vol. 114, January to June 1917, is now ready and may be obtained by writing to this office.

**S**EVENTEEN copper-mining companies distributed \$91,669,281 in dividends for the first half of the current year, as compared with \$65,046,051 during the corresponding period of last year.

**W**HAT kind of postal facilities exist in parts of Mexico, such as Chihuahua, is illustrated by the fact that a letter sent from this office on March 5, 1912, has just come back marked, in French and Spanish, "Returned owing to interruption of communications."

**R**EFERRING to the use of alpha-naphthylamine in flotation, as patented recently by Mr. Harry P. Corliss, we are able to state that since the use of it was introduced at the Magma mill, in Arizona, the tailing has been reduced to 0.3% copper, as against 0.6% formerly, on a 4 to 4½% feed. Mr. Corliss has another patent for the use of nitro-naphthalene.

**A**NNOUNCEMENT is made from Petrograd that it is intended to place many Russian mines in charge of Americans. This is said to have been decided by the Mining Commission of the Ministry of Trade. It is also reported that American capitalists will be offered the island of Saghalien, or the Russian half of it, for exploiting petroleum and coal deposits. All this is important, if confirmed.

**S**T. JOHN DEL REY, the deepest metal mine in the world, is, as our readers know, a gold mine in Brazil. According to the latest report the shaft is now 6800 feet deep, and yet the manager is able to state that "a change has undoubtedly taken place in the lower horizons [levels] which seems favorable both as regards the quality of the mineral [ore] and also as regards the size of the lode, as shown by its sectional area." We congratulate Mr. George Chalmers and his excellent staff.

**Z**INC-PRODUCTION is far below the present capacities of the mines and reduction-works. This has led to a consideration of possible new uses. It is pointed out that the excessive demand for iron and steel has resulted in a shortage of galvanized sheet-metal; likewise tin-plate is harder to get, and sheet-copper is selling at almost prohibitive prices. Considering the applicability of sheet-zinc to many purposes for which galvanized and tinned sheet and sheet-copper have ordinarily been employed, the New Jersey Zinc Company has decided to erect a sheet-zinc mill at Palmerton, Pennsylvania. This

may encourage a permanent increase in the utilization of zinc in that form. The price of sheet-zinc averages today about 7½ cents per pound more than the spelter from which it is made. The cost of rolling is small compared with this difference, thus indicating an opportunity to enlarge the demand for the metal in that direction.

**E**STIMATES of cost have been hard hit by the War, especially if they were such as might be considered sanguine even in time of peace. Thus the Chile, or Chuquicamata, forecast of producing copper for 4 cents per pound may be compared with the 9 cents that is declared as the average of producing copper "at the plant" during the last quarter. To this cost "at the plant" must be added 3.75 cents per pound for freight and insurance—both abnormal just now—and marketing, so that the real cost is 12.75, which is in violent contrast to the cheerful 4 cents of the prospectus.

**I**F we have failed on occasion to be impressed by the doings of the Mining and Metallurgical Society of America, we are all the more glad to express respect for the manner in which the leading members of the Society assembled to consider ways and means of doing patriotic service immediately after the declaration of war. We have read the account of that meeting as recorded in Bulletin No. 108 and confess gladly that it does honor not only to the group of men participating but to the profession that they represented so worthily. Mr. W. R. Ingalls, as president and chairman, steered the meeting most happily and made a number of pertinent suggestions. He said, for example: "In this national crisis we professional men are anxious to know what we can do and to do what we can. Nobody yet knows. We must find out what we can do." Mr. Lawrence Addicks, with his experience as a member of the Naval Consulting Board, described the difficulty of making use of the tremendous volume of offers to serve. He quoted, from a recent proclamation of the President, the statement that "if the metal industries fail, the work of the statesman and the soldier is absolutely useless." A telegram was read from Colonel Robert M. Thompson in which that excellent citizen said: "My advice would be, pull together to increase production and urge every individual to decrease his consumption." That is to the point; it combines the purposes alike of the organization identified with Mr. Bernard Baruch and of Mr. Herbert Hoover, of raw materials and food administration. Capt. Stuart Godfrey, of the Engineer Corps of the Army, made a fine speech crowned by the quotation of Henley's poem on 'Peace and War.' Incidentally he stated that the av-

erage normal size of the gallery made by the tunnelling engineers at the front, as at Messines, is 4 feet high, by 2½ feet wide, and that the average rate of progress is 12 feet per day. Three men work at the face, one excavating, one filling the sand-bags, and one resting. He said: "This is a day of great opportunity, not only for the individual, but for the Nation as a whole. We shall suffer, if the War lasts; we shall feel it, but we shall grow." Yes, indeed, grow great and fine instead of big and fat. After Capt. Godfrey came Major Dwight, whom most of us know better as Arthur S. Dwight. He was one of the first to join the Engineer Officers' Reserve Corps and has taken an honorably prominent part in organizing the First Reserve Engineers, a volunteer regiment recruited in New York. Others contributed to the discussion, notably Mr. P. E. Barbour, who also holds a military commission. Then came an interesting suggestion, made by Mr. S. C. Thomson, well known in South Africa, that American coal-miners should be recruited, and sent under the direction of American mining engineers, to re-open the coal mines around Lens as soon as that district has been re-conquered by the British. Mr. Thomson had written to the Director of the U. S. Bureau of Mines and had received a sympathetic reply. Reference was also made to a resolution forwarded by the San Francisco section of the Society recommending that one or more representatives or commissioners be sent to Europe with a view to ascertaining what was the most useful service that could be rendered by the Society as a whole or by its members.

**THINGS** are not always what they seem. Sometimes we wish they were. Among the items of news that would be labeled 'important, if true' are two appearing in the daily press. The first states that the new 'grenade' employed by our destroyers has proved most effective against the Enemy's submarines, this grenade being sufficiently violent when exploded even within 50 feet of a U-boat to send it to the bottom. Therefore less accuracy of fire, as compared with an ordinary shell, suffices to destroy the assassin of the seas. This report is given some measure of dignity by being tagged as a 'Special Dispatch' from Washington. Next we are told, from El Paso, that General Gonzales, commanding in Northern Mexico, has expressed sentiments friendly to the United States and to our Allies. "A well defined movement favoring an open break with Germany" has developed, and it is predicted that Mexico will declare war against the Enemy within 30 days. Furthermore, the Mexican government intends to make the Tampico oil-fields safe as a source of supply for the allied fleets by declaring a zone within which traffic will be restricted. This sounds cheerful, but the best is yet to come. It is announced, from the same not wholly reliable source that the mines, mills, and smelters of Mexico are to be placed under the protection (or confiscation?) of the Government of Señor Carranza in order that they may produce metals and munitions for the Allies. The introduction of a device to destroy submarines and the protection of

American mining enterprise in Mexico would be two developments so gratifying as to border on the marvelous. For such a turn of events we hope devoutly.

## The Striking Miners

Since we wrote on this subject, last week, the trend of events has been all the wrong way. Strikes have multiplied and spread in the principal copper-mining districts, particularly in the South-West. At Butte only a tenth of the pay-roll is at work. Circumstantial evidence would appear to indicate that the four recent underground fires in this district were of incendiary origin. The testimony of a survivor from the Speculator disaster shows that the fire in that mine was started by a sub-foreman who ignited the insulation of an electric wire, the lead-pipe covering of which had been broken, in the shaft. The managers have been slow to ventilate these facts because they feared that men would be intimidated from coming to work. However, the suspicion of incendiarism was sufficient to cause many men to stop work several weeks before the strike. In the Globe-Miami district the three big mines are idle, and regular troops have arrived to prevent disorder. The mines of the Clifton-Morenci district are practically shut-down. Bisbee is much in the same plight. Austrians, who constitute a considerable part of the labor element in Arizona, have shown themselves truculent; they have attacked American miners and threatened violence to county officials. On July 5 the President telegraphed to ex-Governor Hunt asking him to use his influence as a mediator. Meanwhile a favorable sign is the evidence of jealousy and antagonism between the I. W. W.—the Industrial Workers of the World, known also as 'I Won't Work'—and the International Union of Mine, Mill, and Smelter Workers, which is headed by Charles H. Moyer, formerly identified with that anarchistic organization the Western Federation of Miners. Mr. Moyer has charged the rival organization, now the principal agent in fomenting these unpatriotic proceedings, with being financed by German money and stimulated by German propaganda. We are slow to believe anything so damnable, but Senator Charles S. Thomas, of Colorado, has come out with a positive statement that domestic war is being made behind our backs "by individuals in the employ of our enemies." The sheriff at Clifton has stated in print that it is difficult for him "to believe, especially at this time, that any loyal American would contemplate anything which might in the slightest degree cripple the Government of our country. The closing down or hindrance of the great copper industry in this section would prove a direct blow, and a heavy one, to the Government of the United States." It would indeed; and yet, Mr. Sheriff, you must know that nearly 50% of the men on the pay-rolls of the copper mines in Arizona are Americans only from the fact of domicile. They came to the United States to obtain higher wages; most of them do not speak our language; and only a few of them have become citizens in spirit as well as in form.

The problem of labor-control in these copper-mining districts is largely that of disciplining a mob of uneducated aliens, for whom the fact of the United States being at war is only an opportunity to make unreasonable demands upon their employers. In our last issue we published, under 'Mining News,' the demands made by the union at Miami and the straightforward reply made by Mr. C. E. Mills, the manager for the Inspiration Consolidated Copper Company. The demands indicate a 'hold-up' during time of war. That is all that need be said of them; they include the abolition of the contract-bonus and of the sliding-scale, besides a minimum wage of \$6 for all men working underground. We are informed by an engineer, not now in the employ of the local companies, that two organizers of trouble at Miami were formerly members of the Western Federation and one of them was a colleague of Moyer during the bitter strike at Houghton. Our correspondent listened to the open-air speech-making, and informs us that there was very little said about the scale of wages, but a great deal about the 'rustler's card,' which is simply the black-list of those known to be fomenters of trouble, sometimes legitimate labor-leaders, but usually lawless agitators. Our correspondent has talked with a great many American miners, carpenters, and engineers and has ascertained that these had no wish to strike. The miners are "disgruntled over the cost of living and some blame it on the mining companies," he says. At Miami breakfast costs 30 cents; lunch (put up at a restaurant), 40 cents; supper, 50 cents; \$10 per month is paid for a room, 25c. for the round-trip fare in an automobile, and \$1.35 for the hospital fee, making in all \$56.30 per month for necessities as against wages at \$5.40 per day, or \$151.20 per month. Our informant himself lived in this way; he asserts that a man and wife can live at Miami for nearly the same cost as the single man, so that he is of the opinion that the strikers are "unreasonable." It is not the cost of living but the spending for luxury that has impoverished the mine-worker. The statement has been made that the miner can save no more at \$5.50 per day than he could formerly when his wages were \$3.50. This is untrue, if any idea of thrift be implicit. When wages were \$3.50, the miner could save \$1; now, granting an increase of 50% in the cost of living, he should save \$1.75. He does not do so, but that is not the fault of his employer. The idea that the copper company must increase its scale of wages in proportion to the dividends it pays is neither just nor practicable. It would work a hardship on other forms of industry, notably gold mining. The Ford system of paying extravagant wages may prove beneficial to a particular business while it is prospering, but it means the diversion of labor from other sources and the continuous fomenting of unrest. We agree that it seems inequitable that the copper companies should gain so greatly from the abnormal market created by the War while other businesses are suffering from the same cause, but we do not see why any further part of their dividends should go to laborers that are already receiving 60% more than

before the War. If the profits of the copper companies are to be taxed, they should be taxed by the Government for the benefit of the nation and for the success of the struggle in which we are engaged.

## The New Metallurgy

Hydro-metallurgy of the common metals had a brief vogue about 70 years ago, and aroused the enthusiastic hopes of the mining world. There are fashions in technology as in other things, and back of them lies a compelling principle. It is a part of the spirit of progress, which the biologist would call variation. An invariable metallurgy would be possible only in a world of shrunken intelligence. It is associated with the empiricisms of mastercraftsmanship, exaggerating the importance of the 'cunning' workman hedged about by secrecy. The earlier development of hydro-metallurgy coincided with the beginnings of conscious strength in the field of chemistry when men realized that they were exchanging the juvenilities of an art for scientific understanding. Scarcely more than a hundred years ago the phlogiston theory of combustion still inflamed the imagination of scientific enquirers. Although overthrown by Lavoisier near the end of the 18th century, the notion lingered far into the 19th. The first half of the last century was essentially a period of investigation into chemical laws and of weeding out the absurd medieval conceptions of pseudo-science. It is not surprising that the chemists, in the flush of epoch-making discoveries, should then have challenged the supremacy of Vulcan. It was at this time that Ziervogel worked out the delicate balance between iron and copper in an argentiferous matte, enabling him, by a complicated and equally delicate method of roasting, to extract the silver as a water-soluble sulphate. Augustin had preceded him with a chloridizing roast of copper matte to admit of leaching the silver chloride in hot brine. Following on the heels of these came the hyposulphite system, which endured until replaced by the cyanide process. For the treatment of copper the Longmaid-Henderson method was brought forward about 1842 in an effort to solve the problem of cheap and high extraction from cupriferous cinder coming from the pyrite-burners at sulphuric-acid works; this consisted of chloridizing the copper by a final roast with salt, condensing the gases and vapors, and leaching the residual 'cinder' with water and tower-acid, whereby the copper, gold, and silver were extracted. These are but examples of many hydro-metallurgic processes that aroused interest before the impetus of mechanical improvement, accompanying the reduction in cost of power-generation, gave to pyro-metallurgy a decided lead. The principle of mere bigness also had much to do with this development; enlargement of shaft-furnaces, deeper blast-penetration, water-jacketing of the smelting zone, and finally the bessemerizing of copper matte, coming to its consummation in capacity and economy through the Great Falls type of huge basic-lined converter. Perhaps pyro-metallurgy may not have

reached the limit of its evolution, but a new science has come to maturity as a lusty younger brother of chemistry. Electro-chemistry has renewed the assault on smelting. Mr. A. E. Drucker says this week in our Discussion department that "present-day smelting methods of extracting copper . . . will be replaced gradually by a combined roasting and hydro-metallurgical treatment on the spot." A similar prophesy was made boldly several years ago by Mr. Pope Yeatman. These opinions point the direction of metallurgic advance. Other conditions must soon give way to practices more scientific and savoring less of the muscular metallurgy of Tubal Cain, such as the forging of steel that will ultimately be set aside through control of the physico-chemical relations of its constituents to produce the qualities desired. Clearly the future development of metallurgy will be in the utilization of wet recovery and electrolysis on the one hand, and the direct use of energy in the form of high current-density in the electric furnace on the other. This seems to be indicated further by the growing possibilities not only of high recoveries from ores by flotation but by the possibility of producing cleaner concentrate than ever before, and also by the making of suitably refined salts for reduction, all of which will be demanded by the newer metallurgy.

## Opportunity for Small Ore-Producers

Small producers of lead will be interested in the circular issued by Mr. Clinton H. Crane, the chairman of the Committee on Lead, a sub-committee of the Council of National Defense, calling for offers of that metal at the rate of 8 cents per pound. We reproduced the circular last week, and we direct special attention to it as the embodiment of a principle that we hope will be expanded in the administration of the work coming under the purview of other committees for supplying raw materials to the Government. Complaint has been general because the organization of the committees on metals seemed to exclude participation of the independent producer in the prevailing high prices. As a result the agitation for State smelters, and for other means of control to ensure a fair deal, has been intensified recently. Now comes Mr. Crane, saying in his circular, "If you do not own a smelter, may we ask you to instruct the smelter which smelts your ores to furnish one-sixth of the lead-content of the ore which it accepts from you in July on this Government order and notify them that you will accept in settlement for that amount of lead in your ore the price that the Government is paying." That price is 8 cents per pound, a material improvement over the  $4\frac{1}{2}$  cents that the smelters have been paying on acceptances. The small shipper will point sarcastically to the "one-sixth" of the metal-content to be paid at the higher rate, and to the joker in the phrase that limits this enjoyment to those whose ore the smelter "accepts." The imputation of favoritism apparently has a peg to hang on; that must be admitted. Even Mr. Crane must concede it. Never-

theless, it is a symptom that the Government recognizes its duty to treat equally the offerings of the great and the small. It would be interesting to see what would happen if shippers familiar with accurate sampling, but having no contracts with the smelters, were to offer ore of favorable composition in response to the Government's call. It is doubtful if it would be rejected. The difficulty is that the owners of small mines, who are being crowded out of the boom-market today, lack the financial nerve to maintain their rights. A man may have moral backbone enough to fight for his democratic privileges, but he must also have a large financial cord in his spine to carry the war into the smelting company's preserves so that it may become aware of the invasion. It is for this reason that we have urged organization as the surest and most rational means of gaining recognition from the smelters. In his inner consciousness the small shipper must realize that he rarely can deliver a large tonnage of ore on a long-time contract. He may talk about three carloads a week when making an offer, but when the time of delivery comes it too often happens that he may deliver three carloads in the first week and then stop until he has developed more ore. Likewise, having neither adequate means for sampling, nor proper training for doing it correctly, he over-guesses the metal-content of his ore. To the smelter, who must look ahead in calculating furnace-charges that will maintain a nearly uniform metal-burden and invariable slag-type, without which economical working-conditions are impossible, it is of the utmost importance to have dependable supplies of ore at command. Until the small producers can render themselves dependable by effective organization they will suffer as a class because of the general shortcomings of the individual. On the other hand, if 40 small operators with mines tributary to a single shipping-point were to form an association, maintaining a sampling-works, experienced samplers, and an assay-office, with a good business man as general manager, and this organization could guarantee 20 carloads of ore per week, of known composition, we believe the smelters would be ready to make contracts. Whenever dozens of such organizations in a State are associated for doing business on a larger scale, the moral force of numbers and their consequent responsibility will soon make them a power in the metal world. We have sympathy with the hardships of the small worker; he is indeed crowded out of the banquet-hall, but effectiveness comes from momentum, and momentum is a product of factors in which mass is more easily attained than velocity. The power of democracies lies in the association of groups rather than in the possession of a potential. The ability of the small ore-producer to reach the market and to receive respectful treatment lies in association. Through joining an organization he will be forced to take his own measure more correctly, and the development of such groups of independent producers, enjoying both technical and financial credit, will lead to a recognition that men standing alone, and having but a dribble to offer, cannot expect to command.

# DISCUSSION

*Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.*

## The Development of Flotation

The Editor:

Sir—On this late date I find in your publication an article written by Rudolf Gahl on the 'Future Development of the Flotation Process' in your issue of December 30, 1916. Dr. Gahl's interesting observations still hold good, although they are at this time nearly one year old and that means a lot in the flotation process. He discusses in this article my patent No. 807,501, and I would like to add a little to the cold legal language in which such patents are naturally written.

In my work in the flotation process, which dates back to 1903, I never have been and I never am, up to this present date, a believer in what is known as the 'adhesion' theory of the flotation process. One of the detriments to the flotation process is our distinction between organic and inorganic chemistry. Of course, there is no such thing, and it is only a term of convenience. Students of the flotation process are mostly accustomed to either organic or inorganic work, and will often overlook the possible reactions between substances belonging to either class, yet the formation of compounds between organic and inorganic substances is very well known and I believe plays an important part in flotation. The formation of insoluble soaps, such as those of magnesia, alumina, lime, and barium, will undoubtedly influence the process very materially.

Dr. Gahl, in the latter part of his article, makes the observation that he finds a great deal of support for the assumption that froth is caused by water-soluble substances. We have, like a red thread going all through the process, a combination of sulphide minerals and hydrocarbons or their derivatives. We can also take almost any flotation agent and extract something water-soluble out of it. We can take that same agent after the extraction is made and its usefulness is materially decreased. This shows that the soluble substances are of great importance, and it is my theory that a chemical reaction between the mineral and these soluble substances takes place. When I described in my patent a sulphide-coating I had in mind not only a sulphide mineral but a sulphide compound which I believe formed between the so-called organic oils and the so-called inorganic minerals.

Since this patent was applied for I have spent close to 15 years more or less on experimentation on the flotation process and have practically verified this theory, that is, that the flotation process depends for its success upon the presence of water-soluble substances which actually react with the mineral and also form certain

insoluble soaps. Insoluble oils may be present and may help the process, but solely through the action of modifying the surface-tension.

The successful float means to obtain the proper reagent (mostly of organic character) to promote the proper chemical reaction between the mineral and this reagent, and to select modifying agents to obtain the right surface-tension, without, however, interfering with the chemical reactions of the water-soluble substances; and both reagents must be used in quantity insufficient to cause chemical enclosure of gangue-particles by excessive frothing.

A. SCHWARZ.

Webb City, Missouri, June 18.

## Fire-Protection in Shafts

The Editor:

Sir—I am interested in learning the best methods of preventing shaft-fires in vertical and inclined shafts. I have seen no recent articles on this interesting phase of mine-safety, and I would appreciate a discussion of fire-prevention in shafts.

Take the case of an inclined shaft, say 68° dip, of three compartments, timbered with hemlock laths, dry, containing steam-pipes, pump-discharge pipe, and electric cable; the shaft is up-cast seven months in the year and down-cast the remainder of the time. In case of a fire the current of air would undoubtedly reverse from down-cast to up-cast. On the assumption that the shaft will be up-cast when fire breaks out, how shall we guard this shaft to control the flames? Two solutions present themselves. The first is the usual type of protection. The discharge-line from the pump is tapped at every level, a valve inserted, and a rubber hose, 15 to 50 ft. long, connected. Assume that fire has broken out on the 15th level, and must be fought from the 14th. The head, if the valve were opened wide, would be over 1400 ft. Provided that two or three men could hold this hose with that terrific pressure and that the hose did not burst, could they play down on the fire in an up-cast shaft? The heat would be great and I believe that their efforts would be fruitless. We could only seal the shaft and let the men in the mine take their chances through the other exits. The other solution is a modification of the Grinnell automatic sprinkler system. Three sprinkler-heads would be placed every 25 ft. or 50 ft. in the shaft, one in each compartment. The sprinkler-lines could be connected to the discharge-pipe from the pump and thus have the advantage of the full head on the water-column.

The heads could be so placed that when the fusible plugs melted the full play of the water would be on the hanging side and from there drop to the foot. The result would be a curtain of water. There is one strong objection to this system. The fire could crawl up the cedar-blocking behind the laths before the laths would catch fire, and since the play of water would be on the laths the crawl of the fire in the blocking would render the scheme valueless unless blocking and laths were omitted from each set where the sprinkler-head is installed. I am desirous of knowing what other methods of fire-protection in shafts are known.

FRANK A. MADSON.

Bessemer, Michigan, June 18.

### The Extra-Lateral Right

The Editor:

Sir—I am greatly interested in V. G. Hills' comment on my extra-lateral right article in your issue of June 23, for it was the desire to stimulate intelligent criticism and discussion of this subject that prompted me to write the series. I might suggest that if any of your readers are interested in contributing to this discussion I will gladly send each one addressing me in care of the MINING AND SCIENTIFIC PRESS, a re-print of a series of the four complete articles. I make this suggestion as it will save unnecessary discussion on points which are fully covered in the re-print, and which were necessarily eliminated to save space in the abstract of two of these articles which appeared in your columns. Referring to Mr. Hills' comment I thoroughly appreciate that there are many extra-lateral complaints that cause trouble but which are never actually filed in court, and that many suits are filed and then compromised before determination by the courts. This, however, is an incident of all litigation no matter what its character. Intimate knowledge of these problems in California and in other Western States during the past 15 years or more leads me to state that the extra-lateral situation has no more than its proportion of this fringe or penumbra of threatened and compromised litigation which inevitably accompanies other equally important property-right problems. The law yet remains to be devised that will be free from such difficulties.

I would take exception to Mr. Hills' conclusion that the litigated cases are only a small proportion of "the host of cases which are not appealed;" it is certainly not the experience here in California and neighboring States; nor do I agree with him when he states that the cause of the multitude of surface-contests "is directly traceable to the apex-law." An examination of the reported cases, and the experience with such cases covering a long period of years, does not support this conclusion. Disputes as to priority of location, exact position of surface-boundaries, performance of the various acts of location and of annual labor, are the major causes underlying such litigation, and the fact that such litigation is common wherever placer claims are numerous is absolute proof that the extra-lateral right is not responsible for most of these

surface cases. The moment the ownership of the surface controls ownership of the vein vertically beneath, it is inevitable that the right to the surface is going to be more frequently and more bitterly assailed and contested than in the past. To argue that diminution of surface-litigation will result from abolishing the extra-lateral right is to ignore the logic of the situation. Every foot of surface-ground will, in such event, have an added value, and there will be just as many 'jumpers' and 'black-mailers' left in the world. I am glad that Mr. Hills and I can agree so thoroughly on the importance and necessity of the complete severance of surface and mineral titles in the event that the extra-lateral right is abolished. In fact I gave Mr. Hills credit for and quoted his excellent statement of the advantage to be derived from this policy, in a foot-note to my original article which was necessarily eliminated from the MINING AND SCIENTIFIC PRESS abstract because of lack of space.

San Francisco, June 23.

WM. E. COLBY.

The Editor:

Sir—I have read with much interest Mr. Colby's dissertation on the extra-lateral right in your issue of June 2. My acquaintance with the mining law is chiefly from the standpoint of the engineer, and the mere engineer who ventures to discuss this subject with a lawyer of Mr. Colby's standing, may seem like one who rushes in where angels fear to tread, but I confess that I have found myself in much the same situation as that of the cynical Persian poet who evermore came out the same door wherein he went, a situation in which I felt that Mr. Colby's article also leaves us. Much of Mr. Colby's argument against the abolition of the apex law seems to be predicated on a fear that Congress will remove that part of the mining code as an offending appendix is removed by cutting it out and putting nothing else in its place. Many representatives of the mining industry and of mining organizations, however, are watching the situation, so it is hardly conceivable that such an atrocity would be perpetrated, and an atrocity it unquestionably would be.

I was surprised at the small proportion of cases due to apex litigation, but just what are considered as mining cases in this summary? I am writing where I have no opportunity to refer to Morrison's or any other reports, but I have seen many cases, such as trespass, master and servant, leasehold, and the like, reported and discussed as mining cases because they arose in connection with mining, but if we are to consider only such questions as are peculiar to mining, would not the proportion of apex-cases exceed the 1.9% quoted from Shamel? Mr. Colby quotes from Charles S. Thomas of Colorado: "Now the vast amount of mining controversy—and I am speaking of numbers of actions—has not been apex-litigation. They have been the most expensive and the most far-reaching. They have perhaps resulted in the greater proportion of injustice; but the conflicting (surface) locations have produced the multitude of cases, a small

percentage of which perhaps reach the Court of Appeals, but whose aggregate has burdened the prospector and locator with an expense almost unbearable." Note that these cases "have been the most expensive and the most far-reaching. They have perhaps resulted in the greater proportion of injustice." Is not the fact that a law works an injustice a potent argument in favor of providing means for its elimination? Instances of such injustice are numerous and well-known. The Butte litigation had its origin in the extra-lateral right. It has been stated that a certain wealthy Californian bought a run-down mine, simply because he realized the possibilities of an apex-suit against his rich neighbor. After the expenditure of thousands of dollars in attorneys fees, geologists, and engineers, the defendant won the case, the judge deciding on plain common-sense grounds, although he stated that the plaintiff's contentions as to geological conditions were entitled to consideration. A more technical judge might have decided differently. This case probably is not reported, as I think it was not appealed, the plaintiff having died before the decision. In another case a company spent many months and thousands of dollars developing a supposed blind-lead. After obtaining a gratifying showing of ore, ordering new equipment, completing tests and making plans for a mill, they were served with notice of suit by their neighbor, on the pretense that their so-called blind-lead was merely the faulted portion of a vein having its apex on the neighbor's ground. When any system opens the way to practices that are little short of blackmail, and gives the strong a chance to oppress the weak by ruinous litigation, we are justified in taking steps to correct it, even though it appear drastic at the outset.

It is a notable fact that many neighboring companies in different mining districts have voluntarily agreed to disregard the extra-lateral rights they might have against each other; they have accepted the vertical planes as their boundaries. Such agreements have been entered into by some of the large mining companies of the country, not because they were afraid to stand up for what was rightfully theirs, but, as a straight business proposition, because they recognized the futility and the ruinous nature of such litigation as apex-suits usually entail.

Note the last sentence of the quotation from Senator Thomas. Why do we have conflicting surface locations? Aside from the man who goes out and deliberately jumps a claim, the one who makes a conflicting location does so for the purpose of obtaining an extra-lateral right on a vein which exists in the senior location and is so situated that it will cross one of the end-lines of the latter on its dip. A potent argument in favor of the abolition of the extra-lateral right is that it will do away with conflicting locations, excepting, of course, those made for the avowed purpose of claim-jumping. There can be no doubt that such a change would be radical and would call for other changes as well, but I do not see wherein the difficulties will be insuperable nor do I think that the laws need be as "profoundly amended" as Mr. Colby suggests. He himself states, in his first conclusion, that in nearly every

case where the extra-lateral feature has been incorporated in the laws of other countries it has been abolished eventually. My own experience has been confined to this country, but I have read and heard many statements, particularly with reference to British Columbia, that such abolition has been accomplished without confusion and that the general effect has been beneficial.

I have been told that in the boom-days of Leadville it was not uncommon to see several groups of men within the area of one claim, each sinking madly in an effort to be the first to reach a vein and claim a discovery. I do not think any one would wish to impose such a requirement under present-day conditions, but Mr. Colby seems to fear that such might be a necessity if the extra-lateral right were abolished. Every one, I think, must recognize the fact that the abolition of the extra-lateral right will entail a modification of the requirement of discovery; but need this modification be so radical, or do away with such rights as a discovery would naturally confer? In other words, the fact that a discovery might not be required in every case need not do away with certain indisputable rights that it would confer if actually made. An actual discovery in a controversy over the character of land would have just as much weight as ever, and perhaps more. The discovery of a vein should entitle the discoverer to locate one or more additional claims on the dip. I believe that it might be practicable to carry the policy still farther and allow the location of mining claims on geologic evidence. It has been held before the courts and the Land Department as well that such indications as would put a man of ordinary prudence on his guard as to the mineral character of a piece of land would preclude its entry under the agricultural law. This does not actually require the visible presence of mineral of value, and there have been numbers of coal-land cases so decided where there was no outcrop within miles. If such evidence is sufficient to preclude an agricultural location certainly it should be sufficient to sustain a mineral location.

I do not appreciate the weight of Mr. Colby's argument that "such elimination of discovery would destroy the simplest test whereby mineral lands are now practically and easily classified under existing laws so that mineral locators are able readily to obtain the same lands." The actual discovery would always be held to be the most conclusive evidence as to the mineral character of the land. The modification would be that where such an actual discovery were not feasible it would not be insisted upon; but other competent evidence tending to prove the character of the land might be accepted.

In discussing the feasibility of a classification of mineral lands by the Government, Mr. Colby says, "It would mean aggravating delays where mines were discovered in rugged or desert regions remote from centres of travel." Is it his idea that under a law providing for classification a man who might make a discovery in a remote region would be required to wait for Government classification of the land before he could perfect a location? Such a law would be wholly inconsistent with past and present

practice. Our laws provide for the classification of coal-lands, and land once classified as containing coal can only be disposed of by taking the coal into consideration, that is, by purchasing at the appraisal price under the coal-land laws or by making a filing under the non-mineral law which reserves the coal to the Government; but this does not for a minute prevent a man from filing on coal-land that has not yet been withdrawn or classified as such. Anyone who makes a discovery of coal on land not withdrawn or classified may purchase it under the coal-land laws, provided he furnish evidence as to the likely existence of coal. He is not required to furnish evidence of outcrop or actual discovery on the tract that he seeks, provided he can show reasonable geologic evidence as to its character. This is submitted in the form of affidavits with the filing so that it readily can be seen that if we follow out this same principle in our mineral laws there need be no barrier to immediate location of a mining claim wherever an actual discovery is made.

Nevertheless, any classification of land which depends on an opinion, geologic or otherwise, is bound to provoke litigation, and I am coming to agree with Mr. Colby that the proper solution is a separation of surface and underground rights. This should be done by incorporating into every agricultural patent a clause reserving to the Government all mineral existing in the ground conveyed, and making it available for prospecting, provided the claimant to the surface is properly secured against damage. This is only a step farther than the coal-land act of June 17, 1910. It provides that anyone making an agricultural entry on lands withdrawn or classified as valuable for coal must reserve to the Government or its agents all coal therein, and the right to prospect and mine for the same. The act also fixes the means by which the agricultural claimant shall be secured against damage to the surface. The purchaser of the coal under an agricultural claim acquires such surface rights as are absolutely necessary to mining, but one who purchases a tract of coal-land on which no agricultural claim has been located obtains surface-title as well.

My conclusion is that the extra-lateral right is an anachronism. It is bound to go sooner or later, and should be disposed of, as suggested by Mr. Colby, by segregation of surface and underground rights, and also, as he likewise suggests, revision must be general and only after careful consideration by most competent men. To this I might add: if eventually, why not now?

San Francisco, June 25.

### Hydro-Metallurgy v. Smelting

The Editor:

Sir—The present-day smelting methods of extracting copper from table and flotation concentrates will be gradually replaced by a combined roasting and hydro-metallurgical treatment on the spot. Such is proving to be the case with zinc-blende and gold and silver-bearing concentrate. During the next few years we shall see

some remarkable advances in the treatment of copper sulphides by hydro-metallurgical methods.

Why go to the extra expense of handling and transporting copper concentrate to a smelter when it can be treated at the mine at a greater profit by combined roasting and leaching, producing refined electrolytic copper direct? Let us have some discussion on this important subject.

A. E. DRUCKER.

New York, June 28.

### Misfires

The Editor:

Sir—Every miner, like myself, is interested in the matter of safety, and as misfires constitute one of the most dangerous elements of the miner's daily work this particular matter has interested me greatly. I have read with unfeeling interest the several contributions on this subject appearing under 'Discussion' in your paper, and it seems to me that another contribution analyzing all that has been said in the way of experience and suggestion would be timely and appreciated by all who realize the great importance of this subject.

Angels, California, June 20.

### Seale-Shellshear 'Cascade' Process

\*This flotation process was invented by Seale and Shellshear, previously of the Junction North mine, Broken Hill. The patents have been acquired by the Minerals Separation and De Bavay's Process Co. Fleury James Lyster, of the Zinc Corporation, and James Hebbard, of the Sulphide Corporation, have modified and improved the design of the boxes. The latter company has installed the process on the lead mill of the Central mine, Broken Hill, and is making experiments with a view to adapting it also to the zinc mill. The plant consists of a series of five boxes arranged above one another, the total height being about 24 ft. The pulp is elevated to the first box and in cascading from one box to another the necessary agitation is provided without any revolving impellers. The only power absorbed is that involved in elevating the pulp to the top box. On the Central mine considerable savings have been made possible, not the least of which is a reduction of fully 150 hp. in treating the same amount of material, while repair-costs are reduced to a minimum. This plant is displacing a large number of tables. The introduction of the process has widely extended the scope of flotation separation. The Broken Hill South mine is also experimenting with the 'cascades' in the lead-section of their slimes plant, where it is proposed to install six boxes in series, each containing three 11/16th in. water-jets. Lieut. H. V. Seale—one of the inventors—is at present on active service with the A. I. F., while Wilton Shellshear, the other inventor, is with the Burma Mines, Ltd.

## Principles of Flotation—II

By T. A. RICKARD

**BUBBLES.** We saw how the floating of the needle was aided by bubbles of air attached to it. That suggests, but does not explain, the latest and most successful phase of flotation. To understand it we must go back to the small boy's soap-bubble. The man that understands the physics of a soap-bubble has mastered the chief mystery of flotation. The boy, who, as pictured by Millais, watches the birth, ascent, and disappearance of the iridescent sphere of his own making, is the type of our modern metallurgist, who makes the multitudinous bubbles constituting a froth and then wonders to what natural laws his filmy product owes its existence.

To put it briefly, the boy, having dissolved soap in water, holds a little of the liquid in the bowl of his clay pipe while he blows through the stem. The soapy water forms a film that is distended by the boy's warm breath into a lovely sphere, which is lighter than the surrounding air, and therefore rises, while the sunlight falling upon it undergoes refraction into the colors of the spectrum. When the boy blows through his pipe into pure water, he makes bubbles likewise, but they burst instantly. The high tension shatters them. They do not burst explosively by expansion of the air within their envelope, but by lateral displacement of the substance composing their incompletely elastic films. To prevent such immediate collapse it is necessary to lessen the tension, that is, to diminish the contractile force at work in the watery substance constituting the exterior of the bubble. This can be done by introducing an impurity or contaminant. Water has the highest surface-tension of any common liquid, so that the addition of almost any other liquid—such as oil, alcohol, or acid—will lower the tension. The boy rubs the soap between his wet hands and dissolves it in the water. The soluble soaps contain an alkaline base, such as potash or soda, combined with a fatty acid, such as oleic or palmitic, extracted from tallow or oil. The boy uses oleate of soda, a compound of soda and oleic acid. The flotationist uses oleic acid, and much of the early work was done with this thick oil. In both cases, boy or man, playing at bubbles or working at metallurgy, the oil serves to lower the surface-tension of the water and to prolong the life of the bubbles that are made out of this modified water.

Two phases of the subject may be compared: The needle that floats on tap-water will sink in distilled water, because the latter lacks the air-bubbles that assist flotation. Although the tap-water has a lower surface-tension on account of its slight impurity, that effect is less decisive than the aeration. The bubble blown in pure water will break almost as soon as it comes into existence, but the solution of a little soap in the water

will enable a boy to blow bubbles that sail away beautifully. The lowering of the surface-tension by the contaminant lessens the tendency of the bubbles to collapse. We have seen, in the camphor experiment, how the oil would lower the surface-tension not only of the bubble-film but also of the water in which it might be generated; that lowering of the surface-tension promotes wetting, which is antithetic to floating. If, to water on which mineral particles are floating, an addition of alcohol or caustic soda be made, or even the vapor of alcohol be allowed to play over the surface of the water, the mineral particles sink. The intense local contamination of the water has decreased its surface-tension so much as to increase the relative effect of gravity. Instant wetting ensues. It is evident therefore that oil can be used effectively in flotation in two ways: Either in such large quantity as to raise the mineral by sheer buoyancy or in such small quantity as to coat the particles of mineral, in preference to the gangue, and also decrease the surface-tension of the water in such a way as to promote the formation of a stable froth. Luckily the increased wetting power of the water due to the solution or emulsification of the oil is rendered largely ineffective by the oiling of the mineral particles themselves, on the surfaces of which the oil displaces the water and thus prevents wetting, while the lack of adhesion between oil and gangue serves differentially to aid the wetting of the latter by the water.

The changing colors of the bubble indicate that the thickness of the film is not constant; on the contrary, it may vary within wide limits without noteworthy variation of the surface-tension. That makes an important difference between a liquid film and any ordinary elastic membrane. "The tension in a liquid film is independent of the stretching, provided that it is not so great as to reduce the thickness of the film below about five millionths of a centimetre."<sup>1</sup> This result is promoted by the use of a solute that will be strongly adsorbed at the surface of the solution.<sup>2</sup> As the film is being stretched, the new surface formed at the thinner portion will contain less solute, owing to the time needed for adsorption, so that the new surface will be stronger than the old. Likewise, when water has been modified by a relatively insoluble contaminant, the components of the film can so dispose themselves that the surficial forces will be the same everywhere, that is, they tend to remain in equilibrium, including the force of gravity, which otherwise would pull them apart. Thus the tension at the surface

<sup>1</sup>Poynting & Thomson, *op. cit.*, page 137.

<sup>2</sup>Hildebrand. Fig. 2, page 169, M. & S. P., July 29, 1916. Also Willard Gibbs' 'Thermodynamics,' page 313.

of a contaminated liquid is able to adjust itself within fairly wide limits, and a film made of such a liquid can remain in equilibrium, whereas a film of pure liquid breaks at once. A soap-bubble will last for hours, a pure-water bubble persists for a fraction of a second. Moreover, the presence of a contaminant in water may also affect its viscosity, or internal friction, whereby it offers resistance to change of shape. This strengthens the film of a bubble generated in modified water. It has been asserted<sup>3</sup> that a concentration of the contaminant occurs at the surface of such a liquid, causing the viscosity to be

also for the sides of the glass vessel. They last longer than the bubbles blown in oil because they are made out of a liquid containing a decided contaminant, the dye. Next, I blow air more energetically, and I note that when the bubble is about to escape from the blue water it raises the surface into a mound (A in Fig. 13), emerging at the point of it (as at B) as if the air had dragged the water in an effort to overcome a viscous layer. This indeed is the fact. I caught one bubble in the act; it came slowly through the little heap of water and remained poised at the top of the mound, finally breaking away,

FIG. 13

FIG. 14

magnified as compared with the body of the liquid. This statement is well founded.

An interesting experiment<sup>6</sup> to illustrate this phase of the subject can be made by floating kerosene over blue-colored water and then passing air into the lower liquid. When bubbles are formed in the oil, they are short-lived, but they last long enough to indicate that the oil is not a pure and perfectly homogeneous liquid. In such a liquid, the bubble would break on arrival at the surface. The fact that two bubbles touch without coalescing (K, K, Fig. 13) proves that there is a film of variable composition between them. When I blow air gently into the colored water,<sup>7</sup> the bubbles that rise into the oil are colorless. They accumulate at the upper surface of the oil, where they show an attraction for each other and

while the water subsided sluggishly to its level. Finally, I introduced air more rapidly into the water. The bubbles broke through the viscous water-oil interface and carried portions of water with them. These portions slipped from the north (B, B) to the south pole (F, F) of the bubbles and fell away, sometimes not until the bubbles had reached the upper surface of the oil. An intermediate stage is shown by C, C. This water that detached itself from the air-bubble was not a stable film but a viscous coating. It assumed various forms, crescent, hemispherical (D, D), lenticular, flatly globular (E, E), or even shapeless (G). The retention of a form that is not spherical is proof that the force of surface tension is overcome by the high viscosity of the film at the water-oil interface.<sup>8</sup> Occasionally some of the blue water remains as a globule attached to the surface of the oil, as at S. On reaching the oil-water interface the globule (as at W) will merge itself slowly with the liquid from which it originated.

If a similar experiment is made with carbonated water, in which minute bubbles of nearly equal size are generated quickly, one can see the little bubbles, like bright colorless beads, leading a much bigger globule of

<sup>3</sup>Samuel S. Sadtler, in *Minerals Separation v. Miami suit*, 1915. Emphasized recently in the *Butte & Superior* case.

<sup>6</sup>How variously it can be seen and interpreted is shown by the descriptions given by Messrs. Durell, Norris, and Rickard, in *'The Flotation Process,'* pp. 137, 315, 358; also by Messrs. Taggart and Beach in *Trans. A. I. M. E.*, September 1916.

<sup>7</sup>Some of these experiments may seem almost childish to the supercilious, but I can commend them not only as giving insight into fundamental principles but as likely to stimulate thoughtful discussion.

<sup>8</sup>As elucidated recently by A. F. Taggart in the *Butte* case.

blue water upward (as at  $A'$ ,  $A'$  in Fig. 14) through the oil to the surface, where the bubble breaks and the globule of water falls back through the oil in oblatelly spheroidal shape ( $B$ ,  $B$ ). Sometimes two, or even three, couples rise tandem (as at  $A''$  and  $A'''$ ). At the surface of the oil the coalescence of several bubbles may leave one large bubble to which several small globules of water are attached (as at  $C$ ), or globules of blue water ( $D$ ) may remain floating in the oil, as if hanging from the surface of it. Sometimes the bubble may be overweighted and, after rising a little way, it descends ( $K$ ). If the couples collide, the bubbles are released and leave their freight of water, which drops back. The interesting feature is the air-bubble's ability to lift a water-globule so much larger than itself. This is due to the fact that the water comes from the water-oil interface and includes oil.

The amount of the contaminant in the froth of a flotation-cell can be measured by analysis. The concentration in a film may proceed so far as to form a solid, as when using hard water. The use of oil as a modifying agent is advantageous because it is not prone to enter into chemical reactions with impurities in the mill-water even when thus concentrated in the bubble-films; otherwise some other contaminant might be used. Indeed, it is likely that oil will be replaced by some contaminant that is cheaper and that may also induce some desirable chemical reaction. Several such substitutes are now being tried in flotation plants.

The question has been asked, when a bubble is formed in a liquid, is it a spherical hole filled with gas or is it a sac; in short, has it a skin or not? The reply to this question involves the whole theory of surface-tension and bubble-making. When a pure gas is blown into a pure liquid, the bubbles rise rapidly to the surface, where they burst instantly. The gas injected into the liquid is subject to the gas-liquid tension, therefore the surface of the liquid enclosing the portion of gas assumes a spherical shape in obedience to that tension, because a sphere occupies the least space. The liquid in contact with the gas will have a different orientation of its molecules and it will be slightly denser than the internal liquid. These conditions will accompany the globule of gas in its passage upward. The form of the liquid periphery persists but the substance of the liquid in contact with the gas is changing as the bubble rises. An analogy is furnished by the motionless cloud on a mountain. The cloud retains its shape, although its substance is fleeting. Ascend the mountain and you find yourself surrounded by a mist that is traveling at the rate of 20 or 30 miles per hour, or even faster; yet as seen from the valley the cloud seems fixed. The explanation is that the moisture-laden air sweeps into the cold area on one side, either the snowy or shady side of the peak, and there the moisture is condensed to globules of water constituting a fog or mist; these are visibly driven forward, to be expanded suddenly and dissipated into clear air as soon as they pass beyond the cold area, but their place is taken by others coming on behind, so the shape of the cloud persists although the

substance of it is rushing forward at the speed of a railway-train.

Now the important question arises: What is the substance of the film of the bubble as it passes from one liquid into another? The attachment of blue water to the bubble in the water-oil experiment is confusing, because it obscures the fact that, as the coating of water slips away, the bubble acquires an oily film and when temporarily at rest on the surface it is enveloped in an oily film. No blue tinge can be detected, if the effect of reflection from below be avoided. On the other hand, if the experiment be repeated with heavy oil (colored by 'oil orange') and alcohol, it will be found that the bubbles that come to roost at the upper surface of the alcohol are orange-colored. Thus, as scientific theory would suggest, the bubbles take a film of the liquid having the lower surface-tension or less molecular cohesion. In passing from water to oil or from oil to alcohol the bubble has an oily film at the end of its journey. If a bubble were generated in water and passed successively through oil and alcohol, it would have a water, oil, and alcohol film in

FIG. 15

sequence. If the bubble passed in the reverse direction it would have an alcoholic film in the alcohol, the oil, and the water alike, because alcohol spreads over oil and oil spreads over water, the liquid having the less cohesion or surface-tension being pulled by the molecular attraction of the liquid having the stronger cohesion or surface-tension. There is this to be added, however, that the bubble generated in water would have some water in its oily film when in the oil, and some oil in its alcoholic film when in the alcohol. Each liquid in turn serves slightly to contaminate. On the return journey, the alcoholic film, contaminated slightly by the air and by any impurity in the alcohol-air interface, would resist modification by the oil and by the water (forming the lower layers of liquid) because the alcohol would spread over to the oil-air interface and over the water-air interface. Imagine a globule of oil in an air-bubble enclosed by water (Fig. 15): the oil spreads and forms a film to enclose the air. Now imagine a globule of water in an air-bubble surrounded by oil; the water does not spread, because the pull of the air-water and water-oil surfaces is greater than that of the oil-air surface; therefore a water-filmed bubble will acquire an oil film when passing into oil; on the other hand an oil-filmed bubble will retain its film in making the same entry through water.

We have seen that mineral has a selective adsorption for oil rather than for water and that in this respect it differs from gangue. Metallic particles adsorb air, but

this fact is relatively unimportant in flotation because the air approaches them when it is enclosed within a liquid envelope that is contaminated by oil. Therefore the adhesion of oil for the metallic surface becomes the dominant factor. The older notion, that the affinity of air for metallic surfaces played an important part in flotation has been set aside, because of the absence in the flotation-cell of any direct contact between air and mineral. Metallic surfaces, such as those of minerals, are supposed to adsorb air and that is why they are not readily wetted. It may be due to molecular density, coupled with reduction of inter-molecular distance, which is practically the same thing as a reduction of sub-capillary porosity. Adsorption of air would also bear a relation to the higher density of the mineral. Such adsorption plays its part in the older surface-tension processes, such as those of Wood and Macquisten, but in the later flotation processes there is present insoluble oil or a soluble frothing agent, and this renders it impossible for the globule of air to come into direct contact with the mineral. It is not the air, but the film around it, that provokes the attachment of the bubble to the mineral.

Now let us consider the air-bubble made in water containing an impurity that decreases its surface-tension. In the language of flotation we would say that this impurity is a contaminant modifying the water. As soon as the air enters the water it assumes a globular form as before, but when the bubble reaches the surface it persists; it does not burst at once. The bubble in the water is a spherical hole occupied by air; the air has displaced the water and is enclosed by it; the water-surface in contact with the air is in a state of tension as compared with the interior body of water, and that causes contraction into spherical shape. The surface-tension has been lowered by the contaminant so that the bubble-film is in a state of less strain than a similar film of pure liquid, hence a diminution in the tendency to contract and to collapse. Moreover there is a tendency for the contaminant, whatever it be, to concentrate at the air-water surface; there is a differentiation of the constituents of the liquid, causing the surface to differ slightly in composition from the bulk of the solution and so to accentuate the modification due to the presence of the impurity. The bubble-film or air-liquid contact adsorbs the contaminant until equilibrium is established, and the contaminated liquid of the film carries some of the contaminant all the way to the surface, despite the interchange between molecules or particles of the contaminant on the way up. This differentiation and concentration of the contaminant at the surface of the water in contact with the air-bubble may indeed be likened to a film or membrane, so that the bubble may be regarded as a sac, but it is a sac the substance of which is not fixed while the bubble is moving upward through the water. It cannot be regarded as enclosed within a definite film until it reaches the end of its journey, and even then the film is co-terminous with the surface at which it rests, and the play of light upon it shows that the re-arrangement of

its substance is still in progress, as the excess of liquid drains to the south pole. The variability in the surface-tension due to the shifting of the contaminating particles is essential to the longevity of the bubble-film. That brings us to a recognition of an important factor: viscosity.

**VISCOSITY.** This is defined as the internal friction of a liquid or its resistance to a change of shape. Two years ago the part played by viscosity in establishing a bubble-film was subordinated to emphasis on the lowering of the surface-tension of the water in the ore-pulp.<sup>4</sup> Since then this branch of the theory has been elucidated by Messrs. Taggart, Beach, and Bancroft.<sup>5</sup>

The addition of alcohol increases the viscosity of water up to about 47%, after which the further addition decreases the viscosity. Alcohol, of course, lowers the surface tension of water, but an experiment<sup>6</sup> will prove that the change of viscosity is the dominant factor in making a froth. If alcohol, to which 5% water has been added, be stirred violently in the glass-jar machine familiar to flotationists there will be no formation of froth, but if the experiment be repeated with tap-water, to which 1% of alcohol is added, then a froth is produced at once.

Such an alcohol-water froth is non-persistent, because the absolute viscosity is low. To increase it we must have a colloidal suspension; for example, the foam on beer. The colloidal protein of beer yields a froth that lasts longer than the bubbles on champagne, which are short-lived, like the alcohol-water foam of the experiment just described. To obtain a froth sufficiently persistent to serve a metallurgic purpose it is necessary to increase the viscosity of the bubble-films. This is one of the functions of the oil, and it is one that follows upon its affinity for metallic surfaces. It adsorbs or concentrates (at the surface of the bubbles) the mineral particles in the pulp so as to form an interface that is more viscous than either the oil or the water or the mixture of the two.<sup>10</sup> It is the presence of solid matter that contributes to the viscosity of the bubble-films in the froth.

If a needle be floated on water by means of a raft made of wooden matches and if a chip of wood be floated to one side of it, one can use a magnet to turn the raft and needle on the surface of the water without moving the chip. This shows that the surface, or water-air interface, has no noticeable viscosity.<sup>11</sup> If, however, the surface be dusted with finely pulverized ore, then the magnet will cause the chip to move with the rafted needle.

<sup>4</sup>However, I pointed to the probability of viscosity contributing to the tenacity of the film, even in the needle experiment on tap-water, and quoted Boys to show that increase of viscosity was involved in the lowering of surface-tension in enabling a bubble to persist. *M. & S. P.*, Sept. 11, 1915, p. 385.

<sup>5</sup>More particularly in their expert testimony at Butte, from which I have quoted already.

<sup>6</sup>Described by Wilder D. Bancroft in his testimony at Butte.

<sup>10</sup>Taggart.

<sup>11</sup>Taggart. He pointed to the fact that the addition of the oil increased the viscosity of the surface so as to cause it to act as a solid within small distances, close to the raft, but considerably less than when the powdered ore was sprinkled upon the oiled surface.

THE FROTH IN A CALLOW CELL

The viscosity has been so greatly increased by the addition of solid matter to the interfacial film that the surface behaves as if it were solid. Next, if a drop of oil, sufficient to lower its surface-tension, be added to the water, the chip will not turn when the rafted needle is moved by the attraction of the magnet. Such increase of viscosity as has been caused by the oil is insufficient to form a resisting medium. Finally, if powdered ore is dusted upon the oil-contaminated surface, again the chip does not move with the raft, because "the surface has

been stabilized and made highly viscous."<sup>12</sup>

If water and kerosene be poured successively into a glass bottle, and if then finely-divided copper, called 'bronze powder', be introduced and the contents of the bottle be subjected to vigorous shaking, and then allowed to remain quiescent, the copper powder collects at the oil-water interface and from it slowly a bronze film will separate itself and become pendant. This, when viewed

<sup>12</sup>I am quoting from Mr. Taggart's testimony, from which the description of the experiment also is taken.

ANOTHER PHOTOGRAPH, SHOWING THE FROTH OF TWO ADJACENT CELLS

by transmitted light, is seen to be a lace-like fabric, like a cobweb that has been long exposed to dust.<sup>13</sup> It is a film of particles of kerosene and water so viscous, owing to the inclusion of the powdered copper, that it hangs like a curtain; it is an adsorption layer of bubble-film matter hanging from the oil-water interface. The presence of the powdered copper has stabilized the film.

It is important to note that such increase of viscosity as prolongs the life of the bubble-film need not be metallic. When pine-oil is added to water, and the mixture is agitated, the froth that comes to the surface of the water is thin and evanescent. When to this there is added lycopodium powder, which is of vegetal origin, being the spores of club-moss, the froth becomes thick and lasting.<sup>14</sup> If the lycopodium be used without the pine-oil, no persistent froth is made. In this case, as with the bronze powder, the effect of the solid is to stabilize the froth by making the bubble-films more viscous. The gangue would serve for this purpose if the particles of gangue could pass into the oil-water interface, but it happens, as we have seen, that the oil exerts a preference for the particles of mineral, so that they are adsorbed preferentially.

Another experiment:<sup>15</sup> When a needle was floated on water in a beaker and a drop of castor-oil was added, the needle did not sink. When another drop of the same oil was added, the globule moved to the needle and adhered to it. But it continued to float. When a drop of pine-oil was allowed to run down the side of the beaker, the needle sank as soon as the pine-oil touched the water, while the globule of oil remained afloat. Apparently the increase of viscosity due to the thick oil counteracted the lowering of the water's surface-tension.

The effect of saponine, noted in Hoover's book as being so detrimental to flotation, can now be explained. Although it does not increase the surface-tension of water, but tends rather to decrease it very slightly, according to Freundlich, it causes a marked increase of viscosity. The result is a good froth; but it exhibits no essential adhesion, that is, the saponine solution is not adsorbed by the mineral. Therefore the froth does not persist and the mineral is not floated.

Any substance that is adsorbed into the oil, or the oil-water interface, of the bubble will pass into the film. If it does that the substance will be floated. Mineral goes into oil in preference to gangue. If a particle of sulphide is in the vicinity of oil and water, the oil-surface of the sulphide grows larger and the water-surface grows smaller, until the sulphide at the last takes a position within the oil. Reversely, a particle of quartz takes a position within the water. The greatest possible area of sulphide that can be covered by the oil is when the sulphide is within the oil; therefore the particles of sulphide tend to encase themselves within the oily substance of the bubble-film and so not only stabilize it but give

themselves the opportunity of being floated to the surface in the froth.

**OIL-FILMS.** In the course of the first trial of the Miami lawsuit, at Wilmington, a series of demonstrations was made in court for the purpose of argument. These experiments were photographed and placed in the record. Some of them are of scientific interest. Fig. 16 shows the curved pipette employed to pass an air-bubble to the bubble-holder, which is a bell-mouthed glass tube. Fig. 17 shows the play of a bubble on the oil placed upon a particle of galena lying at the bottom of a vessel containing water. In A the particle of galena and the bubble-holder are shown. In B a globule of oil rests on the galena. The oil is  $1\frac{1}{2}$  times the volume of the galena particle. In C the air-bubble is adhering to the oil on the galena and drawing it up, forming a neck of oil between the bubble and the galena. The photographs exhibit the affinity of the oil for the air-bubble. If the bubble failed to raise the particle of galena, this should not occasion surprise, as it was much too large—several thousand times bigger than the average pulp treated in flotation. In Fig. 18 similar experiments on particles of unoled galena of a reasonable size—about 20 mesh—are recorded photographically. In the first of this series the bubble-holder is approaching one of three particles, in the second it is moving away with one of them, and in the third with another. In Fig. 19 another series of experiments is shown, but with oiled particles of galena, of plus 20-mesh size. In the third member of this group it will be noted that all of the galena particles are being carried away by the bubble. Two of the particles are adhering to the third particle, which is attached directly to the bubble. Ordinary tap-water was used. These experiments, and others like them, showed that particles of galena will adhere to an air-bubble, whether they are oiled or not. The adhesion takes place even when the mineral carries an excess of oil. Particles of chalcocite do not adhere so readily to the air-bubble when they are unoled as when they are oiled, but the evidence given in this suit was incomplete; moreover it was not shown whether a bubble made out of water suitably modified will, or will not, adhere to an unoled particle of chalcocite. The motion-pictures of these demonstrations cost a great deal of money, but it will be acknowledged now, I believe, that they threw but little light on the theory of flotation.

The adhesion of air, as a bubble in water, to mineral particles is easy enough to prove, but such bubbles, as far as I have been able to ascertain by experiments, will adhere to almost anything that happens to be near-by. Trying some of these experiments recently with Mr. Yerxa, at Miami, I found that a large air-bubble would not lift an 8-mesh particle of chalcocite without a good deal of coaxing, but when a minute (accidental) air-bubble became poised on the chalcocite then the big bubble attached itself to the small one and thereby raised the mineral particle. When the chalcocite was oiled the bubble was lifted without hesitation. Examining the bubble-film, it will be seen (Fig. 20) that the

<sup>13</sup>F. E. Beach, who performed the experiment in the court-room at Butte. R. B. Yerxa repeated it for me at Miami.

<sup>14</sup>Bancroft, who performed the experiment in the court-room at Butte.

<sup>15</sup>Made for me by Mr. Yerxa in the laboratory at Miami.

particle of chalcocite hangs from it when in the water, but as soon as the bubble is taken out of the water into the air, the chalcocite is enclosed between an inner and

FIG. 16

A

B

C

FIG. 17

an outer surface,\* in both of which the oily contaminant is so concentrated as to form an adsorption layer.

\*As elucidated by Taggart at Butte.

The nature of this oily-water interface is shown by another experiment. If water and pine-oil are poured successively into a test-tube and a particle of chalcocite is dropped into it, we shall find (Fig. 21) the particle floating at the oil-water interface in such a way that

A

B

C

FIG. 18

the mineral seems to be in the water, when it is really enclosed within a downward protrusion of the oil.

When a bubble is in oily water it has only one contaminated surface, or adsorption layer, but when it emerges it has two. See Fig. 22. The oil is concentrated at the surfaces in contact with the air, outside and inside, leaving the less modified water between.

Again, when a globule of pine-oil was placed on the

smooth surface of a lump of chalcocite under water, the pine oil was held by the chalcocite as against a bubble brought in contact with it, but when the globule of oil lay on a piece of quartz the pine oil was adsorbed by the bubble. A particle of mineral and a bubble show mutual attraction and if the mineral particle is minute

A

B

C

FIG. 19

it becomes drawn into the interface of the bubble-film. That may be why larger particles are not floated easily. They are too big to be enveloped in this way. The mineral particles are carried within the bubble film, they are not attached to it outside. That may explain why fine pulverization is essential to the success of flotation. Thus we arrive at the idea that it is not the air in the bubble only, but the nature of the film, that affects the floatability of the metallic particles.

The addition of oil to water—in a beaker, for example—causes an oily film to appear at the interface between water and air. When an air-bubble meets an oil-globule they will be mutually attracted and some of the oil will pass into the interface between water and air. When air occupies a hole in water, forming what is called a bubble, the periphery of this hole presents a surface—exposed to the air within—like the surface of the water in the beaker. In each case the oil tends to concentrate at that air surface.

The old idea that the mineral particle attached itself directly to air is now relegated to one side; while this mutual attraction may exist, it plays a minor part because the air when it approaches the mineral in a pulp is always enclosed within a watery film contaminated by oil or some similar substance.

It has been disclosed by microscopic examination\* that the mineral particle is not in direct contact with air, but so enclosed within the film as not to be in touch with air either inside or outside the bubble in a mass of froth. The film raises itself over the particle and wraps itself under the particle, so that the mineral is enclosed within a watery interspace. The film itself consists of an exterior surface in which the oil is concentrated, and of an interior surface in which oil also is concentrated, both of these oily concentrations grading toward the water that lies between them. The oil is concentrated at each gas liquid interface, just as oil concentrates at the surface of water in contact with the atmosphere.

The various experiments described in the foregoing pages have shown that the oil in a pulp, consisting of crushed ore and water, performs three distinct functions:

1. It lowers the surface-tension of the water.
2. It assists in the selection of the mineral particles.
3. It promotes the formation of a stable froth.

Water is a convenient liquid for flotation work because it has a surface tension so high that the addition of almost any other liquid will lower it. The lowering of the surface-tension diminishes the contractile force in water and lengthens the life of the bubbles that are formed by the injection of air; but this lowering of the surface tension has another important consequence: it creates such a variable concentration of oil in the watery film of the bubble as to enable the film to adjust its strength to external forces. This variability of tension is even more important than the lowering of the surface-tension, because it serves to strengthen the film where necessary by lessening the proportion of contaminant at any weak spot. The contaminant will concentrate at the surface of the liquid because by doing so it will decrease the potential energy.

Next comes the selective adsorption of mineral particles by the oily film. The oil wets mineral in preference to gangue; it envelops the mineral, by which it is 'adsorbed' or attracted. This causes the particles of mineral to be drawn into the oily film of the bubbles, which in turn are strengthened by reason of the increase of viscosity imparted to their films by the inclusion of

\*TAGGART

mineral particles. The electro-static hypothesis has been discarded in the latest investigations.

Any substance that will lower the surface-tension of water and be adsorbed by mineral particles would appear to promote flotation. The value of a flotation agent

mineral particles these will be coated with oil and adsorbed into the oily film of the bubbles and rise, whereas, by reason of the tendency of water to displace oil on the surface of gangue-particles, those will become wetted and sink.

'Mineral,' 'metallic,' even 'ore' are used interchangeably in the technology of flotation. The misuse of 'ore' has caused great confusion, for the object of the process is not to recover the 'ore', but only the valuable mineral in the 'ore', rejecting the valueless portion, called 'gangue'. As between 'metallic' and 'mineral', the reference is not so much to substances containing metals, for that would include much of the gangue, such as rhodonite and feldspar, but particularly to minerals having a metallic lustre, which feature appears to be favorable to the adhesion alike of air and oil. 'Sulphide' is another synonym, because the sulphur compounds with the base metals are particularly the object of flotation, but 'sulphide' would exclude the tellurides. At least one sulphide without metallic lustre is amenable to flotation, namely, cinnabar. So is graphite, which is neither sulphidic nor metallic, except in lustre. Likewise certain forms of scheelite respond to flotation, and it has been shown by experiment that a stable froth can be made with lycopodium powder, which is of vegetal origin. So we must be careful in our use of terms. The use of 'metallic' and 'mineral' as adjectives to designate floatable substances is based on a concept of flotation that may soon be discarded. No classification of floatable minerals can be made yet and when it is made it must be based on a better understanding of the physical conditions governing flotation.

The amount of oil required in froth-flotation depends upon three factors: the proportion of mineral to be concentrated, the amount of water, and the degree of aeration. Air and water are needed to make bubbles; these bubbles must be oiled in order that they may engage the mineral in the pulp. The more numerous the mineral particles the greater the number of oily bubbles needed to arrest them. If the amount of water is doubled, there will be only half the number of mineral particles in a unit of space; therefore more oily bubbles will have to be sent in search of them than if they were herded within the smaller volume of water. The idea that a 'critical' proportion of oil—somewhere under 1%—is required to perform successful froth-flotation has no basis of evidence outside the imaginings of a group of patentees and it has been stultified by the operations of 1000-ton plants using 22 or 23 pounds of oil per ton of ore, in Utah and Montana. As Wilder D. Bancroft has said: "The hypothesis of a 'critical point' rests on unverified and unverifiable statements."

**THE HYPOTHESIS.** Let us recall the principal points in the evidence before venturing upon a summary of our conclusions. I write in the plural advisedly, for the evidence has come from many sources and the suggestions explaining it have been borrowed from many writers; the theory, like the practice, of flotation is the joint work of a large number of investigators.

FIG. 20

depends upon its ability to 'adsorb' mineral. Most 'frothers' or bubble-makers by themselves are not satisfactory because they lack this ability, and, in order to correct the deficiency, it is customary to add a 'non-frothing' oil, which is adsorbed strongly by the min-

FIG. 21

eral, thereby promoting successful flotation.\* A froth made with a relatively soluble oil, like pine-oil, can be stabilized by adding a relatively insoluble viscous oil, like fuel-oil. The idea of agitation, whether of the violent and mechanical kind or of the gentle and pneumatic

FIG. 22

kind, is to bring the particles of mineral in contact with the oily films of the air-bubbles. Whether the oil is emulsified before or after it is added to the pulp does not matter at this stage, but the oil must have been presented to the bubbles in a minutely subdivided condition, so that they may acquire oily films and so that those films may come in touch with the mineral particles. In doing so the globules of oil and the bubbles that they contaminate beneficially come in contact with particles of gangue as well as particles of mineral, but owing to the tendency of oil to replace water at the surface of the

\*Bancroft. In his testimony at Butte.

(1) The needle that floats on tap-water will sink in distilled water. Although contaminants have lowered the surface-tension† of the tap-water, it has more sustaining power on account of its aeration.

(2) The bubble blown in distilled water will break as soon as it emerges, but the solution of an oily substance will enable a boy to blow bubbles that sail away beautifully.

(3) The addition of oil lowers the surface-tension and thereby promotes wetting, but the adhesion of the oil to the surface of the mineral particles causes the water to be displaced, so that the gangue preferably, not the mineral, is wetted, and drowned.

(4) Emulsification of the oil provides a means, through the subsequent breaking of the emulsion, for imparting oil in a minutely subdivided state, as needed, for oiling the bubble-films and the mineral particles.

(5) The contaminant, such as oil, in water concentrates at the air-surface and by doing so affords a surface-tension sufficiently variable to be adjustable to shock.

(6) The oil-water interface is more viscous than the body of either liquid.

(7) Oil is attracted and adsorbed by mineral particles, which therefore are pulled into the oily film of the bubbles.

(8) Bubbles will break when they collide unless there is a stable film between them, preventing coalescence. Such stability is furnished by a dissolved substance that adjusts the surface-tension and also increases the viscosity of the film.

(9) A multiplicity of bubbles, or 'froth,' will serve a metallurgic purpose if it floats valuable mineral matter long enough to facilitate a separation from the valueless components of the pulp.

The recent trend of hypothesis—it has hardly the status of a theory—is to subordinate sundry ideas prominent a year ago.\* The direct 'adhesion' of air to mineral particles is not so vital as was supposed, because air and mineral rarely come in direct contact in the flotation process; usually either the air-bubble has an oily film or the mineral itself has undergone oil-filming. The lowering of the surface-tension of water is still a fundamental factor, but this modification of the water is recognized as chiefly important not for the first consequence, which promotes the wetting of the mineral, but for its secondary result, which is to create a variable tension on the surface of a bubble-film, and thereby strengthen it greatly. The addition of acid has ceased to be essential, it having been found that alkaline water is better for the treatment of many ores. The acid, like the oil, is supposed to serve more than one purpose:

(1) To adsorb on the gangue and aid the wetting of it.

(2) To promote the flocculation of gangue-particles and the separation of them from the valuable mineral.

†The layer of liquid subject to surface-tension has a thickness less than the radius of molecular action. R. S. Willows and E. Hatschek. 'Surface Energy,' page. 8.

\*'The Flotation Process,' 1916.

Fine grinding of the ore is recognized as necessary, not only to separate the mineral from the gangue, but to assist the making of a froth rich in mineral. No longer is the mineral supposed to be buoyed by the bubbles, as if tied to a cork, but the minute particles of mineral are believed to be drawn into the bubble-film, so that, to pursue the simile, the life-preserver of cork surrounds and encases the thing to be floated. The idea that a fixed proportion of oil to ore is necessary has gone with the supposition that oil only will perform the absorptive function necessary to a stable froth. Colloidal sulphur, sulphur di-oxide, and salt-cake have been proved effective agents in froth-flotation; and we may expect a steady increase in the discovery of such substances until oil, which is expensive, is discarded. The part played by emulsification and the formation of colloid hydrates are becoming recognized as possibly important factors. The violent type of agitation has been found unnecessary, and, thanks to recent litigation, it is likely that the use of compressed air under low pressure will supplant the power-consuming devices of an earlier period. The trend is toward simplicity both of treatment and apparatus. When air and a cheap modifying agent are found adequate for the making of a mineral-bearing froth then the flotation process may be deemed fully developed.

THE GEOLOGY of the Telkwa district in British Columbia has recently been reported upon by Victor Dolmage who finds occurrences of interest. Among these is a characteristic type of copper deposit, assumed to be new, although similar occurrences are not uncommon in the basin region of the south-western United States and north-eastern Mexico. This consists in magnetite segregations accompanied with chalcopyrite, bornite, and tetrahedrite often associated with native silver, the latter being disseminated through the magnetite in the form of rounded grains. The ore is found in veins varying from a width of a few inches to four feet, cutting the Hazleton group of andesites, quartz porphyries, and tuffs. They are mineralized as a result of two distinct epochs of vein-formation, one following the intrusion of the Coast-range batholith of quartz diorite, which was supposedly injected during Jurassic time, and the other following the Bulkley eruptives occurring in the Tertiary age and bringing in diabases, lamprophyres, and soda-syenite porphyry. The earlier solutions deposited in the veins, in the order named, quartz, epidote, hematite, pyrite, zinc-blende, chalcopyrite, bornite, chalcocite, silver-bearing tetrahedrite, and galena. The later solutions deposited quartz, much hematite, epidote and calcite with pyrite and chalcopyrite. The district, as might be supposed from the description given of the characteristics of the veins, is one capable of yielding only moderate amounts of high-grade ore from pockets of superior enrichment and from the careful cobbing of ore derived from the wider veins.

CHINA-CLAY is in sharp demand at the present time, the domestic grades being quoted as high as \$20 per ton at Eastern points. The best imported fetches \$35.

# What is a Metalliferous Mineral?

By L. O. HOWARD

Most persons would probably reply off-hand to the above query that a metalliferous mineral is a mineral containing a metal or metals. I might query further, "What is a metal?" I confess that I have always believed that I knew the answers to these questions and that they were axiomatic. However, I have been disabused by a document recently sent out to one of my legal friends by the Commissioner of the General Land Office at Washington.

For the past six years there have been mined in eastern and south-eastern Utah ores containing vanadium, uranium, and radium, present in the mineral carnotite in certain Jura-Trias sandstone beds. Lode locations have been the invariable method of entry. The shallow depth of most of the ore and the lack of deeper exploration have made the locators content to proceed without patent. This has been shown to be an unsafe procedure in certain cases. Lately, due perhaps to unsettled conditions, many claims have been surveyed for patent. In the Green River area in Emery county a petroleum reserve was established on March 14, 1912, as Petroleum Reserve No. 25, Utah No. 2. This covered most of the carnotite area and antedates many of the locations. Application for a patent to a certain carnotite claim was filed on September 24, 1915, consequent upon a location made on January 4, 1914. On May 25, of this year, the Commissioner of the General Land Office states that the question "now arises of the metalliferous or non-metalliferous character of the mineral sought." The entry was based on a location claiming a portion of a lode, vein, or deposit "bearing uranium and other valuable minerals," and it was stated in the application for patent that "the mineral found is carnotite ore."

The record appears clear up to this point. The claim was located and worked in good faith, assessment and patent work done, survey for patent made and accepted, and all requirements of the law fulfilled. The ground was undoubtedly open to entry and patent if containing metalliferous minerals, according to Section 2 of the Act of June 25, 1910, as amended by the Act of August 24, 1912 (35 Stat., 697), which provides that "all lands withdrawn under the provision of this act shall at all times be open to exploration, discovery, . . . , and purchase under the mining laws of the United States as far as the same apply to metalliferous minerals." Now comes the answer to the query, "What is a metalliferous mineral?" or perhaps one had better say, "What is not a metalliferous mineral?" Let me quote from a letter of the Director of the U. S. Geological Survey, of March 7, 1917, to the Commissioner of the General Land Office in relation to this case. The Director says: "Deposits

of carnotite or other radium-bearing ores are mined primarily for the production, not of the radium itself, which is chemically a metal, but of radium salts, which are non-metallic. Metallic radium is seldom, if ever, produced, and the non-metallic salts, chiefly the chlorides and bromides, constitute the article of commerce. The radium ores may be considered in the same category as potash, limestone, or common salt, which, though the salts respectively of the elements potassium, calcium, and sodium, classified chemically as metals, have uniformly been considered by the courts, the Department, and in mining law as non-metalliferous minerals, as are borax, . . . and similar substances. The question is somewhat further complicated by the fact that the radium occurs only in extremely minute quantities in carnotite-bearing ore, carnotite being a mineral which contains uranium and vanadium. These ores, however, are earthy and non-metallic in chemical character.<sup>1</sup> Vanadium is not even chemically a metal,<sup>2</sup> and although uranium is chemically a metal, . . . as are calcium, the basic element in limestone, and aluminum, the basic element in clay . . . , such limited use as it has in the arts is almost exclusively as an oxide or other salt. The Survey believes that carnotite is *not* a *metalliferous* mineral in the sense in which the term is used in this act." The Commissioner quotes, in further support of his ruling, Dr. George P. Merrill, head curator of geology, U. S. National Museum, who, in his treatise on 'The Non-Metallic Minerals, Their Occurrence and Uses,' says, "Uranium is never used in the metallic state, but in the form of oxides or uranates of soda and potash, and finds a limited application in the arts."

On the basis of the above opinion the Commissioner has allowed the claimant 30 days in which to show cause why the entry should not be cancelled. The Commissioner apparently bases his ruling on the following premises:

1. Radium is not used in the metallic state but in the form of certain salts, such as bromides and chlorides.
2. Vanadium is not chemically a metal.
3. Uranium, although chemically a metal, is principally used as an oxide or salt.
4. Therefore carnotite, which is the economic mineral containing radium, vanadium, and uranium, is a non-metalliferous mineral, analogous to borax, salt, limestone, and potash.
5. Land containing only non-metalliferous minerals is not subject to entry under the terms of the Act with-

<sup>1</sup>Equally true as to some forms of hematite, as for instance, certain Mesabi iron ores.

<sup>2</sup>What is a metal?

drawing petroleum lands from entry as mining claims.

With No. 5 we have no quarrel, since the law is explicit in this respect. Considering first No. 1, although it is true that at present, for reasons well known to those familiar with radium and its uses, it is deemed expedient to market radium in the form of its salts, it becomes pertinent to enquire into certain phases of its use, considered in a broader spirit than is shown in the opinions quoted. What is the function of the salt and to what does it owe its uses? For what is it valuable? We may say without question that all its uses are due solely to the properties of the radium itself, without regard to the form in which it may be. It may be contained in barium chloride or common sand. The entire value depends wholly on the content in metallic radium. The salt, then, is not valuable owing to any particular property of its own. Convenience merely requires that, for easy and efficient use, the radium be carried in some container or packing. What this container may be is immaterial, so that it be harmless. The barium chloride or other salt performs the function of a carrier or container, and this is its sole function. One might as well consider that nails were sold in kegs, because a keg of nails *per se* was especially valuable, rather than buy the keg of nails for the sake of the nails themselves. A keg happens to be a convenient container. An evidence of the importance of the metallic radium is the present insistence that all radium salts be rated in terms of the metallic radium, for it is the metallic radium that is important, not the salt. As to No. 2, it is obvious that a strict interpretation places the metallurgists, manufacturers, and users of steel in the category of those who use meaningless and incorrect terms to describe their products. Does No. 2 imply that ferro-vanadium is not a ferro-alloy? If it does, our definition of alloy needs revision. Webster gives it as a mixture of metals. Also, in what category are we to place tungsten, molybdenum, nickel, aluminum, chromium, and other components of ferro-alloys? Would not the ruling apply to ores of these 'metals' as well?

A comparison of No. 1, 2, and 3 shows some interesting anomalies. No. 1 defeats the entry because, though radium is chemically a metal, its use is not as a metal; while vanadium is used as a metal, it is not chemically a metal; and uranium, while chemically a metal is not used as a metal; so that No. 2 and 3 are also reasons for cancelling the entry. Furthermore, how long is uranium to be used principally as a salt? How long was tungsten used only otherwise than as a metal, and how recently was it found possible to make tungsten wire? Does the Survey intend to say that vanadium and uranium are to have, or do have, but slight use in the metallic arts? If we adhere to the time-honored definition of an alloy, we must admit that the use of vanadium and uranium in the form of ferro-alloys is strictly as metallic substances. Minerals carrying either of these metals are classed correctly as metalliferous minerals. If not, pray, what is a metalliferous mineral? Wherein is the analogy to borax, salt, limestone, and clay? These are all valuable solely

as such, and not because of the content in boron, sodium, calcium, and aluminum, whereas the salts of vanadium and radium are valuable solely because of their content in these metals. Ferro-uranium is being advertised extensively today, and it is surely possible that uranium may find its greatest use in this form.

Further, is it true that carnotite is, or has been, mined principally for its content in radium? It would seem that if it could be proved that at any time the carnotite ores had been diligently sought, and were exploited, as a source of vanadium and uranium for use in the metallic arts, without regard to, or thought of, the radium contained, this statement would lose its force. Early in 1912 I had charge of certain carnotite mines in the area in question. What my clients sought, mined, and shipped was a material to be utilized as a source of uranium and vanadium, and not of radium; in fact, radium was not even considered. Such a competent authority as Madame Curie had scouted the idea of these ores being a commercial source of radium. Work done by pioneers in Colorado was ridiculed and the term 'radium king' was facetiously applied to the chief exponent of the theory that these ores could be made to yield radium commercially. However, his persistence won success. It was only when the Utah ore was found to be slightly too low-grade for the extraction of vanadium and uranium at a profit that attention was turned to the possibilities lying in its radium-content; and it may be remarked that this particular ore was also rather too low-grade for profitable radium extraction.

For many years previous to the attempt to extract radium, countless attempts were made in Colorado to treat these ores for their uranium and vanadium contents. That complete commercial success did not ensue was due to the process employed and lack of experience on the part of the exploiters, not to say unsuitability of the ore itself as a profitable source of these metals. Previous to the discovery of the large Peruvian deposit, a mill was in successful operation in Colorado, furnishing vanadium salts for the manufacture of ferro-alloys, utilizing an ore as low in vanadium as many of the carnotites and containing no uranium or radium whatever; and much of the market was supplied from this source. This mill is still in operation.

Finally, is there any doubt that the leading producer of radium is also utilizing the vanadium and uranium contents of his ore on a fairly large scale in the metal industry? In fact, the Standard Alloys Co., a subsidiary, markets both ferro-vanadium and ferro-uranium, for the latter of which claims are made that may lead to extended use. Is not, then, a mineral carrying uranium and vanadium a metalliferous mineral in the sense in which the term is used in the Act, as well as chemically? Is earthiness peculiar to non-metalliferous minerals? Is it in any sense a criterion? Are not many hematites earthy, many oxidized ores of copper, of lead, and of many other metals? Are sulphide ores usually composed of metalliferous minerals and oxide ores not?

And what is a metalliferous mineral?

# Oruro Tin-Silver District, Bolivia

By FRANCIS CHURCH LINCOLN

The mines of Oruro were worked by the subjects of the Incas before the Conquest. Francisco Medraño, a Spanish curate, learned of them from an Indian, and in 1595 opened the Socavón de la Virgen and Atocha mines. The mines were developed until their silver production rivalled that of Potosí, by the year 1678. With alternating periods of bonanza and borrasca, the mines of Oruro continued to flourish until the outbreak of the Bolivian war of independence. In the three years preceding this war, the silver mines of Oruro paid no less than \$40,000,000 in taxes to the Spanish Crown. As these taxes were one-fifth of the production, the output must have been at least \$200,000,000. The Bolivian revolution resulted in a complete paralysis of the mining industry. It was not until 1885 that revival occurred, when the Chilean Compañía Minera de Oruro purchased the ancient Socavón de la Virgen mine and began work. More recently, this company acquired the Itos property which is separated from the Socavón by the San José mine. The latter mine was purchased by the Compañía Minera San José de Oruro, also a Chilean corporation. These companies control the output of the district, which at the present time is of greater value for its tin than for its silver. According to M. G. F. Söhnlein, the silver production of the Oruro district in 1915 was 780,000 oz., while the normal monthly production of tin concentrate by the Compañía Minera de Oruro is from 2500 to 3500 quintales and that of the Cia. Minera San José from 800 to 1000 quintales.

Oruro, with its 25,000 inhabitants, is second only to La Paz in importance. It is on the Antofagasta-Bolivia Ry., 147 miles south-easterly from La Paz, and 575 miles north-easterly from the Chilean port of Antofagasta. Railroad connection is possible also with the Pacific coast by way of Viacha over the Arica-La Paz Ry. to Arica, Chile, or over the Southern Railway of Peru to Mollendo, Peru; while by way of Uyuni it will soon be possible to go by rail to the Atlantic coast at Buenos Ayres, Argentina. Oruro lies on the Bolivian plateau, at an elevation of 12,120 ft. above sea-level. To the westward, beginning at the outskirts of the town, the Oruro hills rise to heights of from 1000 to 1700 ft. above the plateau.

The Oruro ore deposit is noteworthy as presenting the best-known example of tin-silver veins. Special interest attaches to this type of deposit both because of its rarity outside the Republic of Bolivia, and because it forms a connecting link between pneumatolytic and hydrothermal deposits, tin being characteristic of the former and silver of the latter. The country-rock of the Oruro district is quartz porphyry intrusive through Paleozoic

shales. The porphyry is probably of Tertiary age, and may be more closely classified as a dellenite porphyry. It contains large phenocrysts of quartz and orthoclase and has been highly altered in the vicinity of the veins, as shown by micro-photographs made by Romaña,\* who has exhaustively studied the district. The shales are dark in color and frequently occur as included fragments and blocks in the porphyry. The veins worked on all

three properties form a single linked system which extends in a north-westerly direction diagonally across the northern part of the Oruro hills. The main vein, known as the Purísima, has a strike of about N. 15° W. on the Socavón ground, but has many bends and angles, and develops a westerly strike at the Itos mine. Its dip is likewise irregular, being at times as flat as 50°. The width varies from 3 to 8 ft. The vein splits into numerous narrow stringers around blocks of slate in the Itos ground which re-unite when the vein passes into the porphyry on the further side. A depth of 1250 ft. has been reached on the San José property. The veins are generally filled fissures with the filling 'frozen' to the walls, but occasionally a fault separates the vein from the country-rock and in places the filling penetrates the wall-rock without a distinct line of demarcation. As a

\*Boletín del Cuerpo de Ingenieros de Minas del Perú, No. 57 (1908).

rule, when the veins enter the slates not only do they break up into stringers but the tin disappears, though the silver persists. The primary ore minerals are pyrite, cassiterite, argentiferous tetrahedrite, argentiferous jamesonite, and a little galena. The gangue-minerals are those of the country-rock with a little vein-quartz. The tetrahedrite contains about 5% silver and the jamesonite 0.2%. Cassiterite and tetrahedrite both occur as irregular patches in the pyrite, at times separate and at times intergrown, but the tetrahedrite displays a tendency to occur as stringers, while the jamesonite is found mainly in the form of tufts of fine radiating needles in druses in the pyrite. In an interesting variety known as 'ring ore,' pyrite cores are seen encrusted with cassiterite, while the remaining spaces are filled with tetrahedrite and jamesonite. The order of the ore-minerals is therefore as follows: pyrite, cassiterite, tetrahedrite, jamesonite. The pyrite stage, however, overlaps both the cassiterite and the tetrahedrite stages, while the cassiterite stage overlaps that of the tetrahedrite. Thus, while the deposition of tin was in part contemporaneous with that of the silver, the silver precipitation continued for a longer period. Rich silver chloride ores formerly occurred in the oxidized zone extending downward for several hundred feet, but these were exhausted in the early days. Along with the hornsilver ores were present tin ores known as 'pacos' containing from 4 to 5% tin, and from 6 to 9 oz. silver per ton. These were cast aside, but recently have become the object of exploitation. They are soft and porous, and contain cassiterite, clay, and iron oxides. At times the cassiterite in the 'pacos' is white and pulverulent, and it is then called 'white tin'. Below the oxidized zone there was found a zone of secondary enrichment from which high-grade silver-sulphide ores were extracted in the Colonial period. Underneath the secondary sulphide enrichments is the primary ore which has shown no sign of impoverishment in depth.

From the offices of the Cia. Minera de Oruro, in the city of Oruro, an ancient cross-cut tunnel, the Socavón de la Virgen, whence the mine takes its name, extends to the Purísima vein. The main workings of the Socavón mine extend to a depth of 725 ft. below this tunnel. The mine is worked through an incline-shaft which cuts the Socavón de la Virgen and extends to the third level, 400 ft. below. From the third level a winze has been sunk on one of the branch veins, near its junction with the Purísima, to a depth of 325 ft. Ore from the Itos mine owned by the same company is brought across the Oruro hills by means of an aerial tramway. The San José mine of the Cia. Minera San José de Oruro has a depth of 1250 ft., making it the deepest tin mine in Bolivia. The Socavón mine uses electric power, developed by oil engines. Jackhammer drills are employed in the mine. A considerable amount of the stoping is from ancient fillings and pillars. The mine timbering consists mainly of dry-walls. About 25,000 gal. of water per diem is bailed from the mine. Miners are paid three bolivianos per day, which, at the present rate of exchange, is equivalent to about \$1.00. H. F. Grondijs is consulting engi-

neer for the Cia. Minera de Oruro as well as for Abelli & Co. in the Pazña district.

All the ore is hand-sorted on the surface and the picked ore shipped by rail to the mill.

Owing to scarcity of water at Oruro, the mills of the Cia. Minera de Oruro and the Minera San José are situated on the Antofagasta-Bolivia Ry. at Machacamarca and Poopó. The ore is given a chloridizing roast and the silver is extracted by hyposulphite lixiviation, at the same time leaching and precipitating what little copper is present. The lixiviation, tailing is then concentrated to recover the tin, the tin concentrate, locally known as 'barrilla', containing from 65 to 70% of that metal. The Machacamarca mill is under the superintendence of M. G. F. Söhnlein. The extraction at this plant is about 80% of the tin and 85% of the silver in the ore.

ZINC ORE for retorting is roasted to a low-sulphur content. 'Faulty' sulphur, as it is known in the technology of the art, is the sulphur remaining in the calcine in the form of sulphide and as soluble zinc sulphate. This is distinguished by determining the sulphur combined with lead and calcium, and deducting that from the total sulphur found. The metallurgist assumes that the 'faulty' sulphur exerts a deleterious effect on the zinc recovery, while the sulphur present as calcium sulphate and as lead sulphate is not released from combination in retorting. Edward M. Johnson, superintendent of the Eagle Picher Lead Co., says that it is still an unsettled question whether the detrimental effect of the sulphur held by zinc in the calcine is due to chemical reactions taking place in the retort, thereby retaining zinc as a sulphate, or whether it is because of poor condensation of zinc-vapor. He states as his experience that no means has been found for overcoming the difficulty, and the old rule remains true that "one per cent of 'faulty' sulphur retains two per cent of zinc". Sulphide sulphur in the calcine has a bad effect in forming matte, which exerts a highly corrosive effect on the retorts. "The fireman, in order to save his retorts from 'butchering' does not carry the distillation as far as he might otherwise do, with a consequent loss of zinc in the residue. On the other hand, if the fireman insists upon working off the furnace a high retort-loss ensues through the absorption of zinc."

CHEMICAL industries will figure at the third National Exposition under the auspices of the American Chemical Society at the Grand Central Palace in New York during the week beginning September 24. The advisory committee consists of Charles H. Herty, chairman, Raymond F. Bacon, L. H. Baekeland, Henry B. Faber, Colin G. Fink, Bernhard C. Hesse, A. D. Little, Utley Wedge, and others. This will be the most notable representation of American progress in chemical manufacture that has ever been made. There will be meetings of the Chemical and other societies, with addresses by the foremost scientists of the country. The United States government is also taking a hand in the exposition, and will contribute in many ways to the interest of the occasion.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## ALASKA

NEW DEVELOPMENT ON KNIGHTS ISLAND AND FIDALGO BAY.—THE STRIKE AT THE KENNECOTT COPPER MINE IS STILL IN FORCE BUT A SETTLEMENT IS ANTICIPATED.—ACTIVITY NEAR VALDEZ.

W. A. Dickey, of Landlock, is developing what is known as the Rua property near Rua cove on the east shore of Knights Island. This property was bought by W. A. Dickey and Fred B. Snyder, the latter of Minneapolis, last fall. It is a large pyrrhotite vein carrying copper. The development to date consists of a 500-ft. adit and about 300 ft. of cross-cuts from this adit. The orebody is exposed on the surface at intervals by open-cuts for about 400 ft. and the outcrop can be traced for 2000 ft. Under ground 300 ft. of development has been done this spring under the supervision of Thomas Blakney, the engineer in charge. Fifteen men are regularly employed. A water-driven Ingersoll compressor furnishes power for two jack-hammers, which work effectively. Development will be continued during the summer, and it is expected that a large body of low-grade copper ore will be blocked out.

At Fidalgo bay the Alaska Mines Corporation, under the management of Byron Wilson, is working what is known as the Schlosser property under a bond and lease. The company is shipping to Tacoma from 400 to 500 tons of copper ore monthly that will average about 13% copper. Twenty-five men are employed, and all mining is done by hand. The ore is conveyed from the mine to the bunkers on the dock by a Trenton aerial tram. The ore occurs in irregular lenses in a shear-zone and is a very good grade of chalcopryrite. In prospecting for the high-grade lenses considerable low-grade ore is being found that may be milled at some time in the future. The mine is opened on three levels by adits. Recently a lens 80 ft. long by from 5 to 10 ft. wide was found on the lowest level. This is the largest body of shipping-ore so far found during the intermittent working of the mine in the last seven or eight years. This discovery makes the future of the property look good.

At Cordova the strike at the Kennecott Company properties is still on. The men are camped at Blackburn, four miles from Kennecott. Saloons at McCarthy nearby are closed tight and everything is peaceable and quiet. E. T. Stannard, general manager for the Kennecott company, is to return by June 25 and it seems to be the general opinion that the strike will be settled within a few days. A few of the American and Scandinavian miners employed at the mines refused to affiliate with the strikers on the ground that the men did not keep faith with the company. These men are leaving, or have left the camp. The mill-men and all the men at the lower camp took the same view and are still working. The strike will not affect the mill-output for some time as there is a large stock-pile upon which to draw.

W. H. Seagrave, formerly general manager for the Kennecott company, who now has an office in Seattle, is at McCarthy directing the preliminary work for the Tjosevig-Kennecott company, for whom he is consulting engineer. This company is building a horse-trail from McCarthy to the Tjosevig property, which is across the glacier from the Bonanza mine, preparatory to doing considerable development work during the coming summer.

The Ramsey-Rutherford mine, a small gold mine near the Valdez glacier, nine miles from Valdez, shut-down on June 1.

Some prospecting is being carried on and it is expected that the mill will start up again in a couple of months. This property has been a steady producer for the last three years. It is owned and operated by local people who installed a larger compressor last winter, at considerable expense on account of location, with which they had hoped to keep ore developed far enough ahead to operate the mill continuously.

## CRIPPLE CREEK, COLORADO

OUTPUT OF THE DISTRICT INCREASING.—LOW-GRADE ORE FORMERLY CONSIDERED AS WASTE NOW BEING MILLED AT A PROFIT.—CRESSON CONSOLIDATED HAS A NEW AND RICH VEIN.—NEW DEVELOPMENT WORK.—ROOSEVELT TUNNEL DRAINAGE.

The output of gold ores from the mines of the Cripple Creek district during the month of June, as compiled from the reports of mill managers and district smelter representatives, totaled 89,740 tons, with a bullion value of \$1,064,465.50.

As shown in the accompanying table, local mills of the Portland Gold Mining Company treated the heaviest tonnage of record, 43,650 tons, with a low average value of \$2.016 per ton, and a gross bullion value of \$88,008. This tonnage of low-grade necessarily brought down the average, and it is the lowest on record, \$11.86 per ton. Ore treated at the Independence mill of this company carried a gold content of only \$1.80 per ton. The treatment figures of the several companies and plants follow:

Plant and location.	Tons treated	Average value per ton	Gross value
Golden Cycle M. & R. Co., Colorado Springs .....	32,000	\$20.00	\$640,000.00
Portland G. M. Co., Colo. Springs.....	10,190	19.25	196,157.50
Smelters, Denver and Pueblo....	3,500	55.00	137,500.00
Portland G. M. Co., Victor mill.....	18,150	2.32	42,108.00
Portland G. M. Co., Independence mill .....	25,500	1.80	45,900.00
Rex mill, Kavanaugh lease.....	1,400	2.00	2,800.00
	89,740	\$11.86	\$1,064,465.50

Including the June output the production for the six months of 1917 has totalled 431,738 tons with the gross bullion value of \$6,201,668. The Roosevelt tunnel of the Cripple Creek Deep Drainage & Tunnel Company, according to the measurements taken by T. R. Countryman, consulting engineer for the tunnel company, was advanced 153 ft. in June. The flow of water from the tunnel, passing through the weir at the portal, and flowing thence into Cripple creek, measured 5152 cu. ft. per minute. This is the lowest flow recorded since the tapping of the C. K. & N. water-course in 1912. Work was commenced the last week in June, on a lateral to extend from the Roosevelt tunnel to a point under the Cresson Consolidated Mining & Milling Company's main shaft on Raven hill. A drift has been started from the west side-line of the Old Ironsides claim of the United Gold Mines Company, on Battle mountain, and is headed north-east for the objective point. Low-grade ore is found in the dike in which the drift is carried.

Stock-transfer books of the Cresson Consolidated Gold Mining & Milling Company, and Golden Cycle Mining & Reduction Company closed on Saturday, June 30, preparatory to the pay-

ment of the usual monthly dividends by these corporations on Tuesday, July 10. The Cresson dividend at the regular rate of 10c. per share will amount to \$122,000; the Golden Cycle dividend at 3c. per share to \$45,000. The directors of the Portland and Vindicator Gold Mining companies will meet this week, when the regular quarterly dividends of 3c. each are expected to be declared.

The Granite Gold Mining Company has gone upon a bi-monthly dividend basis and will pay its first dividend of 1c. per share on July 5, to all stockholders of record on June 30. The amount is \$16,500. It is the opinion of men in the confidence of the management that the Granite company will shortly be placed on a monthly dividend basis. The Granite mine is at Victor.

An important new discovery in the Cresson mine was authenticated by A. E. Carlton, president of the Cresson company, the last week in June. A new vein has been opened up at the 14th level of the main shaft, at a distance of 29 ft. from the main Cresson vein. According to the president's statement, the vein is 7 ft. wide and he further states that the ore is of very good grade and will certainly average \$35 per ton.

At the annual stockholders' meeting of the Modoc Consolidated Mines Company, held in Denver the last week of June, the former officers and directors were re-elected as follows: Frank Cannon, president; A. H. Frankenberg, vice-president; Richard Roelofs, Thomas Arneal, Mark A. Skinner, E. D. Avery.

The operations of the company, as shown by the company report, are being steadily enlarged and the upper levels of the old incline-shaft have been leased and are producing. The company is sinking a new vertical shaft on the Battle mountain end of its property on Bull hill and Battle mountain, and has raised from the old workings at the 1100-ft. point to surface. The shaft is being timbered with Oregon-pine square-sets. The timber was held up by a Government embargo for several weeks but was recently released, and is now at the mine in quantity sufficient to square-set to the 1500-ft. level. The Excelsior Mining, Milling & Electric Company, holding a long-time lease on the Longfellow Gold Mining Company's Bull Hill mine, through the Stratton Estate control of that company, has sunk the new shaft to a depth of 300 ft. and has timbered it down to 280 ft. Laterals will be run out to connect with the workings of the Golden Cycle mine, extended into the Longfellow at the 500 and 600-ft. levels, when these depths have been attained. The leasing company was operating through the Golden Cycle and has a large tonnage of ore in sight, but ceased operating through that mine and commenced sinking, conditional on the lease extension. The Stratton Estate will save the low-grade ore rejected by the company operating through the Longfellow shaft, and dumping this low-grade and waste ore on the ground.

### COBALT, ONTARIO

ENCOURAGING PROSPECT FOR A SETTLEMENT OF THE PENDING LABOR DISPUTE.—AGGRESSIVE WORK GOING ON IN THE MINES.

During the fourth week of June ore and bullion shipments from the Cobalt continued comparatively heavy. A total of 10 cars weighing approximately 763,190 lb. was sent out. Six companies contributed to the ore shipments, Nipissing with five cars leading the list. Bullion shipments for the week totalled 313 bars, weighing 363,250.97 oz. and valued at \$238,356.64. Bullion shipments so far during the current year aggregate upward of 5,250,000 oz. valued at over \$4,000,000.

The labor situation is still in a state of plasticity, and, although the strike-vote taken Sunday last resulted in a large majority in favor of striking, as a means of getting the 50c. increase in the present base-wage, the situation is, nevertheless, viewed with more or less optimism. It is generally believed the men will finally, and before calling a general strike, decide upon treating with their employers apart from their union

affiliations either individually or by committee. Should the men follow this course, there would appear to be a possibility of getting a 'high cost of living allowance' instead of the present 'high price of silver bonus'. It was along these lines that a settlement was effected at the Dome and McIntyre mines at Porcupine.

The Kerr Lake Mining Company has declared a special dividend of 15c. per share, payable August 10 to shareholders of record July 5. Half of this dividend will be paid the shareholders and half will be devoted to patriotic purposes. The camp is comparatively well supplied with labor, and in a general way, developments are going forward aggressively.

### PORCUPINE, ONTARIO

THE LABOR SITUATION MUCH IMPROVED.—WAGES ARE INCREASED AND A BETTER CLASS OF MINERS WILL NOW BE AVAILABLE.—THE DOME AND MCINTYRE HAVE HIGH-GRADE ORE AND WILL INCREASE OUTPUT.

The situation at Porcupine has improved during the past week or so, and it is now certain that there will be no general tie-up here. The Dome Mines company has decided to grant its employees approximately 50c. per day above the regular base-wage, which is along similar lines to the action taken over a week ago by the management of the McIntyre-Porcupine. Labor leaders have stated that although the McIntyre management did not deal with and did not recognize the union, it nevertheless has dealt squarely with its employees and will from now on benefit by any favors within the power of the union to confer, in the way of sending the best available men to work at the mine. The fact of the Dome Mines company having followed the lead set by the McIntyre is expected to have a beneficial effect, not only at Porcupine, but at Cobalt as well. At present the Dome Mines employs only 350 men and the increase of 50c. per day will amount to \$175 daily, or about \$5250 per month. During 1916 the company paid \$800,000 in dividends, and at present there is upward of \$700,000 in the treasury, so that the \$63,000 payable yearly under the recent increase in wages will not greatly affect the earning power of the company. In fact, the probable higher efficiency that will result will, it is anticipated, more than make up for the added outlay in wages. Early next week the cross-cut at the 700-ft. level of the Dome will probably enter the orebody 119 ft. wide, that was indicated by the diamond-drill core and mentioned but not included in the estimate of the annual report of the company issued a few weeks ago. This ore is officially stated to carry an average gold content of \$17 per ton. By early August the cross-cut will probably have crossed the entire width of the body, at which time driving, winzings, and stoping will be commenced. With ore once going to the mill from the stopes in this high-grade ore the grade of the mill-feed will probably immediately rise to new high-record for this mine. Hitherto the average grade at Dome has been below \$5 per ton. When it is considered that the milling capacity of the Dome is about 1500 tons per day, it can at once be seen that every \$1 added to the grade of ore treated would increase the daily output approximately \$1500, which would be a large net profit.

On June 27 mining and milling operations at the Schumacher mine were suspended owing to the decision of the directorate and management not to grant an increase in wages to their men, and the impossibility of securing sufficient labor at the old rate of pay. Mill construction, however, is being continued at the Schumacher and the new mill will increase the milling capacity to about 280 tons daily.

The four-weekly report of Hollinger for the period ending May 20 was somewhat disappointing, in that gross production had fallen off to \$92,000 as compared with around \$194,000 during the preceding period. The management, it is understood, is now devoting more energy toward centralizing the

underground work pending the return to more normal labor conditions and cost of supplies. This policy will ultimately result in added net profit to those interested in the mine, and with a return to pre-war conditions a new high record in the rate of dividends will probably be established.

The McIntyre is now employing about 350 men and producing approximately \$150,000 per month. Net profits amount to nearly \$90,000 monthly, which is almost on a par with the Hollinger. Recently, the main orebody was cut by diamond-drills at a depth of 1550 ft. and determined to be over 30 ft. wide of high-grade milling ore. The main body, at the 1000-ft. level, averages around \$12.50 per ton.

It is the general opinion that the period of prolonged strain through which the Porcupine district is passing is at an end, and that increasing prosperity is at hand.

### ELDORA, COLORADO

CHARACTER OF THE TUNGSTEN ORES OF BOULDER COUNTY, COLORADO.—AN IMPORTANT CHANGE WITH DEPTH.—OPERATING COMPANIES.—MILL METHODS COMPARED.—DUTY ON TUNGSTEN ORES SOUGHT.

Tungsten ores follow the same law as the ores of gold, silver, and copper—free-milling at the surface, from which much high-grade ore can be cobbled. In the early days milling of tungsten was an easy problem, but as the ore-shoots increased in depth the ores became more complicated and more tightly bound to the rock in which they occurred and so more difficult to handle; and at the same time they did not offer the amount of free ore that might be cobbled from it as at the surface.

Ores that have been sent to mills for milling have, up to about two years ago, averaged over 10% tungsten tri-oxide, where as now they are of an average of about 5% tungsten tri-oxide. This with the fact that they are of a more complicated nature has caused great changes in the method of milling.

The depth to which tungsten goes is a problem. Some mines give promise of good ore to considerable depth and others do not. The Condor of the Primos company was one that did well to the 900-ft. level. The Clyde mine has great bodies of low-grade ore at 300 ft. and all indications are that they will continue to greater depth, at least the Wolf Tongue company, which owns it, will continue to sink the shaft for investigation.

The Primos company is running at full capacity.

The Vasco Mining Co., associated with the Vanadium Alloys Steel Co., of Pennsylvania, is running steadily. It purchased the upper Rodgers tract and erected a 50-ton mill last year. It also purchased the Boyd mill at Boulder and remodeled it for tungsten ores, and it is running.

The Rare Metals Co., at Rollinsville, has erected a 50-ton mill and is operating it, purchasing ores from the Beaver district. This company has leased mines on Beaver creek and will operate them.

Mr. Caudray, of Denver, has leased the Lone Chance mine on Beaver creek, and also the Smith-Ardouel mill and will mine and mill the ore from this mine.

Jack Clark, who has been in the tungsten business for some time, is mining and milling ores at Stevens camp.

The old Colborn mill, near Boulder, has been remodeled for tungsten ores and will handle it for lessees and from its own mines.

The Wolf Tongue Mining Co., at Nederland, which has been in the tungsten business for 13 years and owns considerable tungsten land, is producing heavily. It mines its own ores and also leases ground. It has ten mines on the company payroll and 20 sets of lessees taking out ore. The Clyde mine is at present the heaviest producer. The Cross No. 1, operated by lease, gives promise of becoming a great producer.

The Bonanza, Star, Orange Blossom, Hoosier, Tenderfoot,

and Town Lot are all on the shipping-list. Several sets of lessees are running the float material over jigs and tables and shipping concentrate. The same plan of operation is used by the Primos company, the Vasco company, and others in the district.

The mills of the district vary in the methods of handling the ores. Some believe, and no doubt have sufficient reason for it, that out one grade of concentrate should be made, and that of a 60% grade. The Wolf Tongue company from years of experience has arrived at the conclusion that two grades are necessary; one of 60% and one of about 20%, called second-grade; and, if necessary, to run the second grade through a mill in the same way as crude ore and thus get the first-grade from this second-grade. Some mills in one operation return all second-grade ore to the re-grinding machinery as soon as made and get the first-grade from it while the crude ore is also going through the mill. This difference of opinion has never been compared to see just which is the best, but the Wolf Tongue mill, from careful work in both ways, has sufficient proof to say that to mix the re-ground sand from the tables or the second jig-product from the jigs with the crude ore and mill both at the same time does not produce the best results. The above statement is based on very careful work and several trials. The best results can be secured by re-running the second-grade by itself and not by treating it with the crude ore. This, however, is a matter of difference of opinion between mill-men here, and each no doubt has secured results to prove his side of the question.

The price of tungsten due to the War has varied. California with its large deposits of sheelite is ready to meet all excessive demands, as well as Bolivia and one or two other South American countries. The talked of tariff on tungsten seems to be coming along well. The opinion of all the old tungsten operators is that a tariff of \$10 per ton will be sufficient to meet all demands and insure a permanent business for some years, and will enable the United States to meet foreign competition. The tariff is a broader question than is generally believed, for it involves the products in which tungsten is used.

Two or three companies are erecting refining laboratories at Boulder for the making of tungstic acid and the Rare Metals Co. at Rollinsville is going to make the acid also.

The future of the tungsten business looks good for many years to come, or until the field here is worked out. As the Wolf Tongue and Vasco companies are directly and indirectly connected with steel companies in the East that will take their products they will be doing business for some time. The situation for the other companies is also good, from all that can be learned.

All the dumps of former years of mining are being jigged by lessees and screened and sent to the various mills. Greater depth has increased the cost of mining, the necessity of pumping water being one reason. The Wolf Tongue company has been furnishing to lessees all equipments, pumps, pipe, and motors, and charging a royalty of 25% on ore taken out. At present it is not offering any more leases to anyone.

### MEXICO

EFFECT OF THE NEW CONSTITUTION ON THE MINING INDUSTRY.—A

SHORT-LIVED STRIKE.—INCREASE IN WAGES ANTICIPATES TROUBLE.

Mining conditions at Pachuca are fairly stable, with the Real del Monte Co. milling 1800 tons per day, the Santa Gertrudis Co. 1000 tons per day, and La Blanca Co. 500 tons per day. Owing to the crazy labor provisions of the new constitution, and to the increasing independence of the Mexican workmen, the mining companies are anticipating a rough and stormy voyage. At a meeting of the laborers recently a strike was called in which all the mechanics, hoist-men, pump-men, elec-

tricians, and the rest participated. In sympathy with them most of the miners and mill-men walked out. The strike lasted about a week, at the end of which hunger and thirst for pulque forced them back to work. This is the usual outcome of these strikes. The Santa Gertrudis Company, however, granted an increase of pay to the workmen. This was probably a far-sighted move, as all the companies will undoubtedly be forced by the Government to accede to the demands of the workmen in the near future. Santa Gertrudis has thus gained the goodwill of the powers that be.

### CLIFTON, ARIZONA

THE ARIZONA COPPER COMPANY ADDRESSES AN OPEN LETTER TO ITS EMPLOYEES IN REPLY TO THAT ISSUED BY THE MINERS.—TEXT OF THE LETTER.

The Arizona Copper Co. has replied to the letter from the union miners, the text of which appeared in the issue of the MINING AND SCIENTIFIC PRESS of July 7. Following is the letter of the company in full:

TO THE EMPLOYEES OF  
THE ARIZONA COPPER COMPANY, LTD.:

In order that you may be fully informed of the answer returned by this Company to the demands recently presented by your Employees' Committee, I desire to put a copy of it in each of your hands. The answer given was as follows:

To the Members of the Employees' Conference Committee, of the Arizona Copper Company, Ltd.

Gentlemen: The conference committee, representing the employees of The Arizona Copper Company, Phelps-Dodge Corporation, Morenci Branch, and Shannon Copper Company, have presented for the consideration of the managers a number of demands.

With regard to these demands The Arizona Copper Company has the following answer to give:

No. 1. That any grievance arising among men working on contracts shall be taken up in regular form by the grievance committee.

The agreement at present in effect between the employers and employees in this district provides that any employee, believing himself to be the subject of unfair or unjust treatment, has the right of appeal through the duly appointed grievance committee of the department or company in which he is employed, and that every employee shall have the right of ultimate appeal to the manager of such company concerning any conditions or treatment to which he may be subjected and which he may deem unfair; under the above provision this company recognizes the right of any employee working either by the day or under contract to use such means in seeking redress of any grievance which he may have.

No. 2. That any employee refusing to accept a contract shall not be discriminated against or discharged for refusing the same.

No men who are working in places where a contract is let shall be discriminated against or discharged, on account of same.

The present agreement fully covers such cases and no further rule seems necessary.

No. 3. That seniority rule must prevail both in increasing and decreasing the force.

This company cannot adopt such a rule in the operation of its mines, as it would serve neither the interest of the employer nor employees generally, and would be in direct conflict with the spirit of the agreement which provides that the right to hire and discharge, the management of the property, and the direction of the working force, shall be vested exclusively in the company. The practice of this company in the past when forces were increased or reduced has had regard both for the efficient prosecution of the work and for the

personal claims of the workmen, as for instance: When preference has been given to married employees when it has been necessary to curtail the working forces. The adoption of any rule that would limit the company's rights in this respect cannot be considered.

No. 4. That time and one-half be paid for all overtime, and that time and one-half be paid to all craftsmen and their helpers for all Sunday work, the 4th of July and Christmas.

Inquiry amongst our employees developed the fact that a large proportion of those who would be affected were such a rule adopted is not in favor of this demand. We will, therefore, defer consideration of it until we can be shown that substantially the majority of those who would be directly affected by it are in favor of such a rule.

No. 5. That the living conditions in this district are such that we are compelled to ask for the Miami scale of wages.

This company recognizes the present conditions with respect to the cost of living, as given by the committee as a reason for the demand for an increase in wages at this time, such conditions being due to the European war, and it is prepared to offer as an offset to the present increased cost of living an increase of 50c. per day to those employees who are receiving on the present scale a base rate of wages of from 25c. to 46½c., inclusive, per hour, and a raise of 25c. per day to employees receiving a base rate higher than 46½c. per hour. This offer to take effect July 1, 1917, and to continue in effect until after 30 days' notice has been given its employees by this company. This offer is made upon the following conditions, viz:

That its employees do not go out on strike, and with the further understanding that such offer will be withdrawn in the event of a strike occurring which shall have the effect of suspending the operations of the company.

The company also desires to notify its employees that in event of a strike it will refuse all guarantees with respect to reinstatement of any employee, upon resumption of operations thereafter.

THE ARIZONA COPPER COMPANY, LTD.

By NORMAN CARMICHAEL, General Manager.

Clifton, Arizona, June 30, 1917.

When demands upon a company are made on behalf of employees through their committee and an answer is rendered, it is customary for such answer to be communicated to the employees generally, especially when offers of compromise are contained, in order to ascertain the wish of the majority as to whether such answer is satisfactory or not. Such a course indicates a proper conception of responsibility on the part of the leaders and shows their respect for the intelligence of the employees they represent.

A strike, involving loss of work to several thousand men and the suspension of operations which sustain a large community, is a very serious matter, and the hasty manner in which the present strike was called without giving you an opportunity to even read the reply which we made to your demands and without giving you an opportunity to show, by your vote whether you preferred to accept the answer given or to go out on strike, indicates that your interests were not consulted in the matter, and that your faith in your leaders is not well placed.

The offer which this Company made of an increase of 50 cents per day to those at present receiving from 25 cents to 46½ cents per hour, base rate, meant that the largest proportion of you would receive this increase to offset the present high cost of living, and which you would enjoy during the continuance of such conditions. Do you realize that this offer was made upon condition there would be no strike, and that, in calling you out on strike without putting these facts before you, your leaders have deprived you of that offer?

THE ARIZONA COPPER COMPANY, LTD.

By NORMAN CARMICHAEL, General Manager.

Clifton, Arizona, July 2, 1917.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—Secretary Lane has directed the Alaskan Engineering Commission to start mining operations in the Matanuska coalfields immediately. Federal mine inspector, Sumner S. Smith, has been named as resident engineer and will take charge of the operations of the mines. The purpose of the work is to furnish an immediate supply of coal to the Alaskan Engineering Commission for its use in the operation of its trains and construction work. It is expected that the mines will be opened up on a comprehensive plan and the work will be carried on under the supervision of Mr. Smith with the co-operation of George W. Evans, district engineer for the Bureau of Mines, stationed at Seattle, and who already has had experience in the field. The reason for this action is that the private operators not having commenced operations on a scale that would insure the Commission an adequate supply of coal, it was thought best for the Commission to operate its own mines for the time being at least. Leasing Unit No. 7, with the equipment on the property, has been purchased by the Commission to obtain an immediate supply of coal and work will be started on Unit No. 12, at Chickaloon, to supplement this. With these two mines in operation the Commission will be assured of an ample supply of coal, not only for its use locally but to supply the Government boats visiting this harbor.

Reports received at Anchorage from Lewis river are encouraging and operators are satisfied that the camp will be prosperous. Breunerman and Hamilton reached their holdings last week and will start operating on June 20. Peterson & Co. started work on June 11. Sam Wagner and partner are sluicing with good results.

The Alaska Copper company has filed location notices in the office of the United States commissioner covering the Silver Dollar, Phoenix, and Black Bear lode mining-claims situated in the Harris mining district.

The officers of the steamer 'Alaska,' which reached Juneau June 21, report that the people of Cordova have been unable to gain any news of the Kennecott strike. It is known that 200 men walked out and that the ore is not arriving as rapidly as formerly, but otherwise there is no further news of the strike. E. T. Standard, manager of the mine, is returning north on the 'Northwestern,' having left Seattle June 19. The Alaska Treadwell company is contemplating the erection of a trestle around the 'cave in' as the most feasible means of getting out the heavy machinery. This will restore the transportation system to its former status and will do away with tramming over the 'high line' through the central crushing plant.

Treadwell, June 30.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—The Mascot Copper Co. of Willcox, controlling 50 claims and operating a railroad 16 miles long between Willcox and the mines, has been taken over by the American Smelting & Refining Co. under a long-time lease. The Mascot company has been shipping between 500 and 600 tons of ore per week. This production will probably be increased.

Willcox, June 20.

On June 27 about 2500 of the 5000 miners employed in the mines at Bisbee went on strike. They demand an increase in pay and better working conditions. The companies most seri-

ously affected are the Copper Queen, the Shattuck-Arizona, and the Calumet & Arizona. The managers of these companies are reported as saying they will close down every mine under their control in the district rather than submit.

The Bisbee Review of July 3 says: Raising their sights, by some action, the I. W. W. at Bisbee, have decided that, in the words of one of last night's speakers at the City Park, "we will not sign peace terms until every other company which now has labor trouble on its hands accedes to the demands of the strikers, in every part of the country." This action followed a similar announcement made by the Butte, Montana, organization.

But for two mass meetings, held by the I. W. W. yesterday, one in the afternoon and one last evening, the day was quiet. No arrests were reported from any part of the district. One Slavonian resident of Bisbee, however, reports having been threatened with personal violence if he continued at work. He was standing in front of the Busy Bee restaurant when accosted by several men. He did not know any of them.

More miners and other underground workers reported for work at the various mines in the district yesterday. The exact increase in the working forces was not obtainable, but it is said to be a substantial one. It is felt and expressed by many men, thoroughly conversant with the situation, that nearly complete forces will be on hand at the mines after July 4, on which day the two companies have declared a holiday.

Many men continue to leave the district for other parts of the country. The railroad ticket offices are crowded before every outgoing train departs. It is estimated that upward of 500 men have left Bisbee in four days. There is another movement of the I. W. W. This seems to be in the direction of the Globe-Miami and Clifton-Morenci districts. During the first day or two of the trouble the influx of I. W. W.'s was considerable. For some reason, attributed by many to a feeling that the strike has been lost, the tide has set in an another direction.

### GILA COUNTY

Telegrams received at I. W. W. headquarters at Miami late on the afternoon of July 2 assert that the metal-mine workers at Jerome will strike in sympathy with the branches that have walked out in the Globe-Miami district. The messages were from the secretary of the Jerome branch of the I. W. W. organization. Local metal-mine workers say that many other camps throughout the country will shortly follow with strike orders in their effort to cripple the copper industry until their demands are granted.

### MOHAVE COUNTY

(Special Correspondence.)—Three Doerr agitators are being installed at the United Eastern mill, which will increase the total daily capacity of the plant to 300 tons or more per day. The crushing capacity of the mill is 400 tons daily, but tank capacity was originally planned on a basis of 200 tons. Six months operation of the plant convinced the management that daily capacity should be increased to at least 300 tons. Development is progressing on both the 565 and the 665-ft. levels, opening up new ore reserves. The main shaft is being sunk 300 ft. deeper, a supplementary plant having been installed for that purpose.

While a large amount of ore is being opened up at the Gold Road property, it is not probable that milling operations will be resumed there for some time. The increased cost of milling and mining is given as a reason.

As high as 340 tons per day has been milled at the new Tom Reed plant. In a supplementary report to the stockholders, the board of directors stated that the company has ore reserves of over 100,000 tons, sufficient to supply the new mill for one year. Development is progressing on the Aztec vein, but shipping of ore to the mill is confined to motor-truck haulage pending the installation of the aerial-tramway. At the Adams Mining Company's property in the Black Range, two parallel veins or fault-fissures have been explored by driving about 350 ft. from where it was first cross-cut from the shaft at the 400-ft. level. On one of them valuable ore has been opened up for 50 ft. In anticipation of a heavy flow of water the main cross-cut from the shaft is provided with a concrete bulk-head and a steel door which can be made water tight, thus protecting the pumping-plant on this level.

Though gold is heavier than tailing dust, it has been proved at the Tom Reed plant that the heat of the sun will cause it to come to the surface. Assays made of the tailing-dump last year by Mr. Rabb, the superintendent, showed that the top half inch of the pond carried about \$15 per ton in gold, while that below was practically of no value. Accordingly the pond was systematically scraped and about \$10,000 in gold recovered. This process is being repeated this year.

Oatman, July 3.

(Special Correspondence.)—On the 400-ft. level of the Adams mine a body of payable gold quartz has been opened up in a vein 350 ft. from the working-shaft. The vein is 14 ft. wide and driving is in progress along the foot-wall. C. H. Palmer, Jr., is engineer for the Adams company and N. A. D'Arcy is manager. The vein parallels one that has been driven for 350 ft. without satisfactory results.

Diamond-drilling will be done to explore the Telluride property adjoining the Tom Reed and the Sunnyside, by J. L. McIver, one of the discoverers of the United Eastern. The same method will be tried at the Mohawk Central by M. J. Monnette. This is the first time this method of prospecting has been tried here, except on the old Moss mine, where the Santa Gertrudis Corporation ran two diamond-drill holes.

J. P. Loftus and J. K. Turner have started operation of a new 30-ton ball and amalgamating-mill on the Oatman Gold Top property in the Secret Pass district.

The Gold Ore Mining Co., adjoining the Gold Road, announces that it has commissioned Otto Wartenweiler, of Los Angeles, to design a mill with a capacity of 200 tons per day. A unit of 50 tons will be built first. Mr. Wartenweiler designed the United Eastern mill.

Oatman, June 24.

#### PIMA COUNTY

(Special Correspondence.)—The Growler mines, 16 miles south-west of Ajo, have been bonded for \$250,000 by a group of Ajo capitalists. The Growler was owned by George H. Morrill, of Boston. It was formerly known as the Colonial Copper Co. There are 26 claims in the group. The mines are worked through a shaft 325 ft. deep and a 200-ft. incline.

Tucson, June 20.

#### YAVAPAI COUNTY

Ninety per cent of the day-shift at the United Verde copper mine at Jerome reported for work on Sunday, following the rejection Saturday by members of the Jerome local of the International Union of Mine, Mill and Smelter Workers of a proposal to submit to the membership a strike vote on the question of joining the Metal Mine Workers' Industrial Union No. 800, of the Industrial Workers of the World, in a strike declared Saturday by the latter organization in the Jerome copper district.

All of the smaller mines, which closed down on July 7 pending announcement of the result of the vote, were at work with practically full forces today.

#### YUMA COUNTY

(Special Correspondence.)—Mining is active in the hills adjacent to Wenden and Salome. At Salome the Navajo Mines, Cobrita Verdi, Glory-Hole, and several others are coming into prominence.

At the Navajo Mines there is an encouraging showing, and an adit on the main vein is being driven. Charles Redall, of the Cobrita Verdi, has recently shipped in machinery from Goldfield, Nevada, and is installing it preparatory to starting work. At the Glory-Hole, with a complete equipment of machinery, including jack-hammers, Ernest Hall, in charge, has men developing that property. The Harqua Hala mine, under direction of John Martin, is developing and is expected to become as prominent again as in the bonanza days when over \$2,000,000 was taken from one level. It is said that a considerable tonnage of ore has been opened up there, but it is of a different character from the ore on the upper levels. It is more base, and carries copper as well as gold. Formerly all ore taken from here was free-milling. The old 40-stamp mill and a complete equipment is on the property. There has been talk of putting in either a concentrating-plant or flotation, as too much of the value is lost by simple amalgamation.

George Easton and E. A. Stent, lessees of the Critic mine, which is owned by George B. Layton, of New York, are steadily operating their property in Cunningham pass and have discontinued leasing to miners and will work the mine themselves. The last car shipped from there returned 1.05 oz. in gold and 19.84% in copper per ton. From two to three cars is shipped from there monthly, and the former lessees were making big money.

The superintendent of the Black Reef mine in Cunningham pass, has been getting chalcopryite from the bottom of his shaft, which is now down 300 ft. Mr. Scott, one of those interested in the Black Reef, and who is also interested in the Superstition and known among his friends as 'Lucky Scott,' has been called to Canada to join his regiment.

Mr. Ormsby, of the Wenden Copper Co., is steadily sinking a shaft to reach the permanent water-level. He is backed by Globe people who are interested in the Old Dominion.

Wenden, June 28.

#### CALIFORNIA

The amount of oil available in the various areas of California has been summarized in a report made to the State Council of Defense by R. P. McLaughlin of the State Mining Bureau. The visible supply of oil has been rapidly decreasing during the past year. A special committee, headed by Max Thelen, of the Railroad Commission, has, for several weeks, been engaged in investigating the oil-supply of the State, which furnishes power for railroads and many other industries of vital importance at the present time. The report dealing with the oil remaining underground has been compiled from production records and well-logs filed with the Mining Bureau during the past two years incidental to the work of protecting the fields from damage by improper well-drilling. Future use of the information will be determined entirely by the State Council of Defense.

#### EL DORADO COUNTY

(Special Correspondence.)—The Cincinnati gold quartz mine, situated 10 miles by auto-road north-west of Placerville, in the Kelsey mining district, now has 10,000 tons of friable free-milling quartz practically blocked-out, and the management is proceeding to have installed a 5-stamp mill of 1000-lb. stamps, to be operated by an oil-engine. Burr Evans, the local mining engineer, states that such a mill will readily crush 25 tons per day of the kind of material to be reduced. No rock-breaker or concentrator will be required. The free-gold will all be recovered on the battery-plates.

The ore consists of a yellow ochre-like material, stratified with numerous small stringers of crumbly quartz, with an

occasional egg-shaped lens of high-grade ore about the size of a foot-ball. The pay-shoot averages 16 ft. wide, and will run not less than \$3.50 free-gold per ton, without including the high-grade lenses. The ore can be mined by auger-boring, light blasting, and picking, and conveyed by gravity through a 250-ft. adit to the mill at a cost of 26c. per ton.

The cost of milling the ore is estimated not to exceed 54c. per ton; thus making a total cost of 80c. per ton for mining and milling. Then, after allowing 70c. per ton for continuous new development work and overhead expenses, it is figured that it will net not less than \$2 per ton. The mine is being operated by Berkeley and San Francisco capital. In this district in the 80's the Kelsey mine was operated for some time at a cost of less than 50c. per ton for mining and milling.

Placerville, July 3.

#### FRESNO COUNTY

(Special Correspondence.)—Dan Yokovich, of Shawmut, Tuolumne county, has discovered what may prove to be a valuable vein of molybdenite-bearing rock in the granite at or near the Inyo-Fresno county line in the Sierra Nevada. Analyses of samples have returned 3.4% of molybdenum sulphide.

Shawmut, July 2.

#### MODOC COUNTY

At Copper Peak, the Valley View Mining Co. is reported as ready to start a new adit at the foot of the mountain. This will cut the shaft and the orebody from which ore was extracted last year at about 1200 ft. depth. There is from 5 to 7 ft. of azurite and native copper. The adit will also cut the white metal nickel-cobalt veins before it reaches the copper veins. The copper ore averages 45% copper and \$4.50 gold. The nickel veins give 14% copper and \$8.40 gold on assay. No assay was made for nickel. Owners of the copper group on the east of the Valley View prospect have given an option on their property to R. Kemp Welch.

Parties in the East are negotiating with Mr. Welch, owner of the Copper Gold group, 16 claims, with from 12 to 14 ft. of oxidized copper ore at surface. In the group are several veins which pan copper. Two veins pan gold.

The mines are within three-quarters of a mile of the foot of the mountain, and are reached from Alturas, 34 miles, on the N. C. O. R. R., by auto-stage, or 14 miles distant from Miller's Ranch station on the same railroad.

Colorado people came in last week and are at work, having secured options and paid some cash on a claim seven miles south. There will be great activity here this summer.

#### SHASTA COUNTY

(Special Correspondence.)—The Noble Electric Steel Co. is constructing a blast-furnace at its Heroult iron-smelter, with a capacity of 30 tons per day. It will be operated in conjunction with the electric-furnaces and is scheduled to go into service within 30 days. Difficulty in securing electrodes is interfering with electric-smelting and plans have been prepared for manufacture of electrodes at San Francisco. It is planned to keep five electric-furnaces in constant operation for the production of pig-iron, ferro-chrome, ferro-manganese, and similar products.

The Afterthought Copper Co. has arranged for the immediate building of a large roaster at its Ingot plant. The copper-zinc ore will be treated by leaching and flotation, according to recent advices. Several buildings are under construction and the mine has been placed in condition for a heavy output. Besides copper and zinc, the developed ore is said to average better than \$1.50 per ton in gold and silver.

The Mammoth Copper Co. has acquired the Keystone copper property on Flat creek, from Robert Strenson, George A. Groto-fend, and William Slennon, of Redding. Four thousand dollars has been paid and the balance will be met in installments. The deal calls for extensive development pending consummation of the purchase.

Prospecting of dredging-ground is active around Redding. The El Oro company is vigorously exploring a wide area north of town, and the Gardella interests are busy along Clear creek. Construction of four dredges by this company will be pressed as fast as lumber and other material can be secured. Several other companies are testing gravel with promising results. It is reported another effort will be made to work the extensive gravel deposits in the vicinity of Igo.

Redding, June 28.

### COLORADO

#### SAN JUAN COUNTY

The Lackawana mine near Silverton has been cleaned out and promises to become once more a substantial producer. The J. B. Smith tunnel, which is in 1200 ft., is once more in good condition. A cross-cut was run at the face of the old tunnel and a vein was found in 15 ft., which has now been followed for 200 ft. The vein is from 3½ to 5 ft. wide, and a stope has been carried up 90 ft. Net returns on a carload of ore recently sent out were \$108 in excess of any carload that has been shipped from there. There is also in another place 3½ ft. of galena.

#### SAN MIGUEL COUNTY

Manager Barnhart of the Mountain Top Mining Co. says that the new mill, recently completed 400 ft. underground in the Mountain Top mine, is doing good work since it was finished several months ago, says the Ouray Plaindealer. He is working three shifts each 24 hours and getting about 80% of the possible capacity of the mill. He has ordered steel-chrome balls for the mill and as soon as they arrive he expects to be able to put through approximately 50 tons of ore daily. Edward Treweek, former mine superintendent of the Wanakah and Vernon mines at Ouray took charge of the mine and mill about one month ago, and the results of his experience and executive ability are already apparent in increased production of both the mine and mill.

### IDAHO

#### SHOSHONE COUNTY

(Special Correspondence.)—As a result of the sale of the Keystone mine, also known as the Blacktail, on Pend Oreille lake, nearly \$250,000 is being distributed to the former stockholders on an issue of 1,746,440 shares at the rate of 13½c. per share. There are upward of 50 beneficiaries, nearly all of whom are residents of Spokane, Washington, and of British Columbia. Volney D. Williamson sold the property to Henry H. Armstead for \$250,000 several months ago. The Keystone mine was acquired and developed to the point of important production by Mr. Williamson and associates, and is now in the possession of the Armstead mines, of which Henry H. Armstead is the controlling owner. Associated with Mr. Armstead is a group of the foremost tobacco manufacturers of the East and South.

The Tamarack & Custer Consolidated Mining Co. will add \$900,000 to \$1,250,000 to the production of the Coeur d'Alene region in the last half of this year, according to estimates. It has been estimated that the equipment is capable of handling 300 to 400 tons per day and of producing 60 to 80 tons of concentrate containing 40 to 48% lead.

The average content of the ore is 8 to 10% lead, 6 to 8 oz. silver, and a small quantity of zinc. The zinc will be saved by flotation. About 250 men will be employed in the mine and mill when operations are under way. The labor and other costs will be \$1500 per day. The cost of production has been running close to that of other large properties of the district, although hauling has been a large item of expense. It is believed this item will be reduced now that a tramway has been installed, especially if a means is found of handling timber on the tramway.

The mill of the Hercules Mining Co. at Wallace is receiving

ore at the rate of 700 tons per day, according to a report received this week. This is 50 tons in excess of its expected capacity. If the report is correct the company is producing in excess of its production for 1916. The official figures for that period show a shipping product of 87,179 tons having a gross value of \$7,278,258. This is at the rate of nearly 250 tons per day and \$90 per ton. The Hercules paid \$1,501,129 for extraction in 1916. This cost now will be greater as a result of higher charges for labor and supplies. It is believed the net profits will be greater than those of 1916, notwithstanding an exceptionally low grade of ore. Much ore from the Hercules mine has gone to the Consolidated smelter at Trail, B. C., and the Day smelter at Northport, Washington. Some of it will now go to the Bunker Hill & Sullivan smelter at Kellogg.

Spokane, July 1.

The Snowstorm Consolidated produced 7400 tons of ore in May, the first month of its operation. The rate of production was a little better in June—probably 7600 tons. The mill has been receiving 240 to 250 tons daily since the start. The extraction was good from the beginning.

The Dreadnaught Mining Co. has cut an orebody and the conditions are favorable for the development of an important tonnage. The first orebody opened in the Dreadnaught,  $3\frac{1}{2}$  ft. wide, was cut at a depth of 730 ft. The average content is 10 oz. of silver, 12% lead, and 4 to 6% zinc. In a better part of the shoot it runs 36% lead, 19% zinc, and a larger quantity of silver.

## NEVADA

### HUMBOLDT COUNTY

(Special Correspondence.)—In the spring of 1916 Lovelocks was much excited over the discovery that tungsten minerals occurred at many places in the vicinity, and many claims were located, followed by the construction of two large concentrating mills. Now Lovelocks is again excited over a new discovery—this time potash. J. C. Smith, Herman Markes, E. F. Hunter, and C. Offers, who had located several claims at the mouth of Cole canyon, 6 miles north-east of Lovelocks, at the south end of the Humboldt range, discovered potash on their claims. L. B. Snipes who saw the rock thought it contained potash, and an analysis proved his guess to be correct. The owners told their friends, and Lovelocks was promptly practically deserted, all hands hurrying to the scene of the new discovery, at the place that has been called Kopatka, where many claims have been located. There is a little soft earthy incrustation, but the best ore, which occurs in large amount, is hard and compact, resembling rhyolite.

Lovelocks, June 26.

It is reported that a discovery of importance has been made in the Seven Troughs Coalition mines at Vernon, where 2 ft. of ore running \$600 per ton in gold has been found.

### NYE COUNTY

(Special Correspondence.)—The shaft-sinking at the White Caps has progressed steadily during the past week. The bottom of the shaft is 120 ft. below the fourth level. One more set of timbers will be placed and then the fifth-station set will go in. The ground has been so hard that piston-drills have been used in the shaft. The east drift on the 300-ft. level has been advanced 15 ft. during the week, through marbleized limestone, and this characteristic has been observed in the vicinity of the orebodies both east and west from the shaft. It seems probable that a new orebody will shortly be reached. In the west drift 300 ft. has been made with no material change in the face. The water has decreased to some extent during the week, and is now easily handled by the pumps. The total flow is 115 gal. per minute. Seven hearths of the roaster have been completed and the drying-hearth will be finished shortly. The crusher-house is complete and ready for operation. The mill will be ready to crush ore by July 1. The cyanide de-

partment of the mill also is ready for operation. The roasting-flue and stacks are not yet completed. Dahl oil-burners will be used for heating the roaster and the material for the burners is at the mill ready for installation. In mill-construction little remains to be done except as noted above.

The manager of the White Caps Extension, O. McCraney, has returned from Goldfield, where he purchased a Hendrie & Bolthoff No. 4 electric-hoist. A 40-ft. head-frame was also obtained. Negotiations are on for a large air-compressor. The first round in the Extension shaft has been shot, and as soon as the machinery is installed, shaft-sinking will be urged as fast as possible.

The installation of the 40-hp. electric-hoist at the Morning Glory No. 1 shaft has been completed and shaft-sinking is proceeding. The shaft has been sampled each day. The last assay, taken from the shaft bottom, shows an average of \$5.65 in gold. The 4-drill compressor is about complete and as soon as the necessary air-pipe reaches the mine machine-drills will be used in the shaft. The development in the No. 3 shaft of the Morning Glory has reached a depth of 40 ft. This shaft is close to the White Caps west side-line, and about 100 ft. north-east from the No. 1 shaft of that company, which for the past 15 ft. has been in pay-ore, with considerable calcite in the hanging wall. The past three days work in the shaft has been in ore with assays of \$40. Two samples assayed \$200 and \$140 respectively. This shaft is being sunk on a lime and shale contact and is developing ore underlying the various orebodies developed in the White Caps property west of the old White Caps Leasing Co. shaft.

In the Amalgamated property the east drift on the 600-ft. level has been extended 16 ft. and is out 364 ft. from the shaft. Work was retarded during the early part of the week by a heavy flow of water from a longitudinal fault carrying good gold ore, evidently the edge of an orebody.

At the Manhattan Consolidated a drift was started along the ore on the foot-wall to determine the length of the shoot, which on the second level was 85 ft. long and 25 to 40 ft. wide. One round was fired in this drift, breaking 6 ft., and the greatest high-grade ore-pocket ever developed in Manhattan was exposed. To a depth of 6 ft. and for 8 ft. in the vein from the foot-wall, manganese mixed with yellow oxide, a soft gouge-like material shows full of free gold. Some of the gold is in crystals, but it is mostly wire and flake-gold. One panning made from the soft material, without mortaring produced \$20 worth of gold with strings of wire-gold welded together. Eliminating the pockets where the gold shows, a sample of the ore was taken, two ore sacks being filled, to get an average of the 8 ft. This sample assayed \$534 in gold.

### WHITE PINE COUNTY

(Special Correspondence.)—The Nevada Consolidated Copper Co. has started up the north half of its new crushing-plant and it is running satisfactorily, handling between 600 and 700 tons per hour, reducing the ore to about  $\frac{1}{4}$ -in. size. Formerly the ore went to the rolls, in lumps the size of one's two fists. The ore carries normally 3 to 4% moisture.

The Consolidated Copper Mines Co. is shipping two cars of 8% ore to the McGill smelter per day from the old Alpha workings. It is an oxidized silicious ore. The mill is handling between 500 and 600 tons per day of 2% ore from the Morris workings. The other unit is expected to be in commission this month. Two drills are in operation.

The old Ward mine is shipping 50 to 75 tons daily. It is being hauled with the Knox auto-trucks.

Several lessees are working on lead-silver ores throughout the county; there are five separate leases on the Hunter mine, 18 miles south-east of Cherry creek. The man in charge representing the Eastern owners charges each shipper \$15 per car shipped. This is paid him by the smelting company as an 'inspection charge,' which the shippers consider exorbitant.

The ores from Hamilton will be hauled to Kimberly and go

out over the Nevada Northern railroad because Mr. Sexton, the manager of the Eureka-Palissades railroad, refuses to handle it. The State Railroad Commission will probably make an investigation.

Steve Pappas, who made the first discovery of gold ore in Willow creek, 100 miles south-west of Ely, a few years since, recently made another discovery on the extension of one of the known veins. On the surface he took out a pocket of 1100 lb. for which the smelter paid him \$591.

Some Salt Lake people have made him a small cash payment and taken a bond on it. Some of the same people did the same on the original discovery, did a little work and quit. There have been several small pockets of rich ore found there during the past three or four years, but they have all been dug out quickly.

The Consolidated Copper Mines Co. has closed contracts with the Nevada Consolidated Copper Co. to mine by August 15, 1918, from its Oro claim, at the entrance of the Liberty pit, 425,000 tons of ore and to mill and smelt the same. At the end of this period the company will continue to mine and treat at least 75,000 tons per annum from the same place for a period of five years.

The Nevada Consolidated also will treat all of the concentrate made by the Consolidated Copper Mines Co. for a period of five years from May 1, 1917. This latter includes sufficient high-grade smelting-ores (equal to about two carloads per day) to make the total 150 tons per day.

The Copper Mines Co. (old Giroux) is treating in its new mill upward of 15,000 tons per month of its ores that average around 2% copper, from the Morris workings. The second unit, of equal size, is expected to be ready for operation some time during July. Delay has been caused by non-delivery of material. On the basis of 25c. copper, with costs at 12½c., when the other unit is in operation, this company should make over \$2,500,000 net during the next year.

The direct-smelting ore, now going to the smelter, runs about 12% copper. The development from the Giroux shaft, on the west side, in and beyond the old Alpha workings, is showing up some rich oxide in bodies up to 50 ft. wide.

The management appears to be in good hands, where the stockholders will get a square deal. Humphreys, Burgess, and Merritt, who have the operating control, are good business men, who desire to develop the property as an investment.

Ely, July 1.

## NEW MEXICO

### DONA ANA COUNTY

El Paso men have taken one year's bond and lease on the Atlas Apex group in the Quartzite mining district. The Atlas and the Apex are the principal mines in the group. Twenty tons of ore was shipped this week from the Willow Creek mine on the upper Pecos to the smelter at Salt Lake City for a test run. D. C. Jackling and other owners of the Salt Lake smelter are reported to have interested themselves in the upper Pecos and Dalton districts. The extensive development work now going on within 30 miles of Santa Fe is said also to be at their behest.

### SIERRA COUNTY

The famous Bridal Chamber mine, at Lake Valley, is again being worked, but for high-grade manganese ore of which three carloads per day are being shipped to the steel mills at Joliet, Ill. One hundred men are employed and two new hoists have been installed.

The Empire Zinc Co. is making a topographical survey of its 42 claims in the Kingston district in the Black range. The Kangaroo Mining Co. will install a gasoline-compressor and machine-drills for the driving of a tunnel 800 ft. from Saw Pit canyon.

### SOCORRO COUNTY

(Special Correspondence.)—The Socorro Mining & Milling

Co. cleaned up 1800 lb. of gold and silver bullion for the first half of June. New ore-bins are being added to take care of the increasing custom business.

The Oaks Co. has increased ore shipments from the Maud S. property. Another lot of burros has been added to the pack-train. The new wagon-road to the Central shaft has been completed and lumber is being delivered at the shaft collar. The head-frame is nearing completion.

Complete surface and underground surveys are being made on the Confidence property and the indications point toward an early resumption of operations at this old producer.

Mogollon, June 28.

## TEXAS

### BURNET COUNTY

(Special Correspondence.)—It is announced that the Texas Graphite Company soon will be re-organized and taken out of the hands of the receiver. The company owns a large deposit of graphite, situated near here, upon which it invested more than \$200,000 in improvements. It is planned to resume the development of the property about August 1. McCarty Moore has installed a graphite-concentrating mill and other equipment upon a large deposit of graphite which he is developing near Llano. He is making shipments of the graphite concentrate to Cincinnati and Cleveland, Ohio.

R. H. Downman, of New Orleans, who is developing a deposit of graphite 30 miles north of Burnet will construct a mill for the purpose of treating the raw material. This property consists of 2450 acres of perpetual mineral rights.

Burnet, July 1.

## CANADA

### BRITISH COLUMBIA

Ore valued at over \$350 per ton in gold, after payment of all freight and treatment charges, has been discovered by the operators of the Emancipation group of claims near Hope. The group from which this ore was obtained is situated on the Coquahalla river, 16 miles from Hope, and close to Jessica station, on the Kettle Valley railway. The property is owned by Michael Merrick, Herbert Beech, and William Thomson, who are the discoverers. It is bonded to C. H. Lighthall at \$125,000. Mr. Lighthall represents New York capitalists.

Recently a shipment of ore was sent to the Tacoma smelter, and after freight and treatment charges were deducted, \$18,295 was netted from 53 tons. The vein is at the contact of slate and diorite and can be traced for almost 2000 ft. It pans free gold for almost the entire distance and in places is 12 ft. wide.

At 23-mile camp, on the Princeton road, large bodies of copper and silver-lead ore are awaiting development. At Jones Lake the Foley, Welch & Stewart interests are diamond-drilling their property recently bonded for \$100,000.

### ONTARIO

(Special Correspondence.)—The La Rose directors have voted \$30,000 for development work on their Violet claim adjoining the O'Brien mine at Cobalt.

The Buffalo Mining Co., of Cobalt, is this year helping its employees to defeat the high cost of living. The mine cleared up the Watash claim for farming purposes, supplying teams, explosives, and labor free for the work. The married employees organized into squads under shift-bosses and each individual in the organization is required to do at least 50 hours work on the farm. The mine furnished the seed and the produce is to be divided among the men in proportion to the size of their families. Sixty miners are in the association and about 20 acres of land has been cleared. J. G. Dickenson of the O'Brien mine is in Nova Scotia; Stanley Graham of the Technical College, at Halifax, is in the Cobalt district; the Huronia Gold Mines are being re-opened by a syndicate composed of Quebec and Cobalt men. J. Young, underground superintendent of the Hollinger mines, has returned from Montana.

The flotation-process is becoming increasingly important at Cobalt. The present users of the process are the Buffalo mines, McKinley-Darragh-Savage mines, the Nipissing mines, the Coniagas mines, the Dominion Reduction Co., the Northern Customs Concentrators, the National mines, and the Trethewey mines. The Buffalo mines, with a 600-ton per day plant, has the largest installation.

Cobalt, June 30.

## MEXICO

### SONORA

An official of Green-Cananea Copper Co., at New York, says he doubts correctness of dispatches from Mexico attributing certain accusations to Secretary Nieto of Mexican department of finance against the Cananea Consolidated, the operating company of Greene-Cananea, as the company is acting and has always acted entirely within mining laws of Mexico. Statements purporting to have been given out by Secretary Nieto state that the Cananea Consolidated Copper Co. had refused to pay taxes on 7702 mining claims, which were overdue and owing to the Mexican government, had moved machinery across the border, closed up its hospital and ejected its patients.

It is true the company has abandoned these 7702 mining claims. This was done in accordance with laws of Mexico and followed the inauguration of the high-rate mining tax put into effect more than a year ago. Failure to pay taxes on mining claims constitutes an abandonment of all rights, and there is no provision in the law calling for any specific notification to the government. The company has paid taxes on all claims retained.

Last April a representative of the stamp-tax office and the principal administrator of the tax at Nogales conferred with officials of the company in Nogales. Nothing further was heard until June 12, when Secretary Nieto telegraphed that if the taxes (which would have been due if the claims had not been abandoned) were not paid within 15 days the right of export of bullion would be withdrawn. As it was manifestly impossible to operate if the company was not permitted to export metals, and as it was an illegal and arbitrary action, it was decided to cease operations before the date set. As to the other charges the official says: "There is no truth in the charge that the company secretly sent out some of the machinery nor in the charge that the hospital was closed and patients ejected. The company left its own physician and staff in charge of hospital patients, and the local Mexican officials arrested them and put a Mexican physician in charge, but the following day released the American physician and attendants and they are now in charge of the hospital under direction of a Mexican agent."

Edward Steidle, engineer in charge of Rescue Car No. 1 of the U. S. Bureau of Mines, announces that Car No. 1 will be at the several places named below, at the times specified: Salt Lake City, Utah, July 1 to July 10; Park City, Utah, July 11 to July 25; Bingham, Utah, July 26 to Aug. 11; Milford, Utah, Aug. 12 to Aug. 18; Eureka, Utah, Aug. 19 to Sep. 1; Sandy, Utah, Sep. 2 to Sep. 15; Scofield, Utah, Sep. 16 to Sep. 22; Castlegate, Utah, Sep. 23 to Sep. 29; Hiawatha, Utah, Sep. 30 to Oct. 6; Sunnyside, Utah, Oct. 7 to Oct. 13.

In case of mine disaster Car 1 can be reached indirectly through the University of Nevada, Reno, Nevada, (headquarters); A. J. Stinson, Nevada State Mine Inspector, Carson City, Nevada; Henry M. Rives, Secretary Nevada Mine Operators' Association, Reno, Nevada; P. A. Thatcher, Utah Industrial Accident Commission, State Capitol, Salt Lake City, Utah; A. G. Mackenzie, Secretary Utah Chapter American Mining Congress, also representative of Coal & Metal Producers Association of Utah, Boston Bldg., Salt Lake City, Utah; H. M. Wolfson, California Industrial Accident Commission, Underwood Bldg., San Francisco, California; and Robert I. Kerr, Secretary, California Metal Producers Association, Merchants National Bank Bldg., San Francisco, California.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

D. M. RIORDAN is in New York.

D. V. KEEDY is in French Guiana.

H. FOSTER BAIN writes from Shanghai.

MORTON WEBBER has gone to southern Arizona.

JOHN ROSS, JR., is in San Francisco from Nevada.

W. S. NOTES has returned from Ashland, Oregon.

ALBERT BURCH has returned from the Coeur d'Alene.

H. G. CANNON is mining in Mono county, California.

A. CHESTER BEATTY is traveling in China and Japan.

C. S. GALBRAITH has opened an office at Webb City, Missouri.

ERNEST A. HERSAM has returned from New York to Berkeley.

E. B. REESE has returned to Los Angeles from San Francisco.

GEORGE J. BANCROFT, of Denver, passed through San Francisco on his way to Idaho.

C. YABE, engineer to the Sumitomo Besshi copper mine, is visiting our mining districts.

C. W. PURINGTON lectured recently at King's College, London, on 'Pacific Routes to Siberia.'

C. E. VAN BARNEVELD passed through San Francisco on his way from Salt Lake City to Tucson.

C. T. GRISWOLD, geologist of The Associated Geological Engineers, of New York, has gone to Wyoming.

J. B. TYRRELL has been appointed Canadian representative of the Consolidated Mines Selection Co., London.

FRANCIS A. THOMSON has been appointed dean of the School of Mines of Washington University at Pullman, Washington.

HERBERT G. THOMSON has been appointed superintendent for the Nevada Packard Mines Co., at Lower Rochester, Nevada.

JAY A. CARPENTER has resigned as general superintendent for the Nevada Packard Mines Co. and is now at Wonder, Nevada.

ROBERT C. STICHT has had to go to Butte, so his address before the local section of the A. I. M. E. is postponed until further notice.

E. S. KING has been appointed manager for the Waihi Grand Junction mine, in New Zealand, succeeding WILLIAM F. GRACE, who has retired owing to ill health.

H. C. HOOVER has been awarded the Cross of a Commander of the Legion of Honor by the French government in recognition of his services in provisioning Belgium and northern France.

A REGIMENT OF ARTILLERY is being organized in San Francisco as a part of the National Guard of California, but with the intention of mustering it into the Federal service on August 5. Mining engineers are invited to enlist. A few commissions are available. Further particulars will be given in our next issue. Communications may be addressed to W. G. Devereux, care of this office.—EDITOR.

## Obituary

W. GUY SCOTT died at his home near Soulsbyville, Tuolumne county, California, June 24, Mr. Scott with his brother, Proctor Scott, for many years operated the Black Oak mine, near Soulsbyville. He was a native of California, having been born at Diamond Springs, in El Dorado county. For some years past Mr. Scott has been employed by the Government as forest ranger.

JAMES E. DYE, well known as a mine manager in Amador county, California, died at the home of his son at Vancouver, B. C., June 25, at the age of 62 years. He was manager for the Exploration Company, of London, in Amador county for several years, where he had charge of the Amador Queen mines. More recently he had been identified with the Bank of Amador, at Jackson.

# THE METAL MARKET

## METAL PRICES

San Francisco, July 10

Antimony, cents per pound.....	18.50—22.00
Electrolytic copper, cents per pound.....	34.50
Pig lead, cents per pound.....	12.25—12.50
Platinum soft and hard metal, per ounce.....	\$103—111
Quicksilver, per flask of 75 lb.....	11.50
Spelter, cents per pound.....	50
Tin, cents per pound.....	20
Zinc-dust, cents per pound.....	20

## ORE PRICES

San Francisco, July 10

Aluminum-dust (100-lb. lots), per lb.....	\$1.00
Aluminum-dust (ton lots), per lb.....	\$0.95
Antimony, 50% metal, per unit.....	\$1.35
Chrome, 40% and over, f.o.b. cars California, cents per unit.....	50—55
Magnesite, crude, per ton.....	\$8.00—10.00
Tin, cents per pound.....	60
Tungsten, 60% WO <sub>3</sub> , per unit.....	\$25.00—30.00
Molybdenite, per unit for MoS <sub>2</sub> contained.....	40.00
Manganese, 45% (under 35% metal not desired), cents, unit.....	33—37

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese.....	\$1.00
46 to 49% metallic manganese.....	0.98
43 to 46% metallic manganese.....	0.95
40 to 43% metallic manganese.....	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

Tungsten has taken a sharp advance, owing to continued and increasing demand, and scarcity of the supply to meet it. From a nominal price of \$20 to \$22 per unit for 60% ore, the price has risen to \$25 to \$30 per unit, and unless indications are misleading it will go still higher. Some ore of low grade has been shipped from the mines at Atocha to Boulder county, Colorado, for concentration.

## EASTERN METAL MARKET

(By wire from New York)

July 10.—Copper is dull and weaker at 31c. Lead is quiet and lower at 11.12c. Zinc is dead and lower at 9.12c. Platinum remains unchanged at \$105 for soft and \$111 for the hard metal.

## COPPER

Prices of electrolytic in New York, in cents per pound.

The weekly letter of Samuel Montagu & Co. of London, dated June 14, contains the following regarding silver: The market has at last left the doldrums in which it has remained for more than a month past. The change was accompanied by an abrupt movement of the price upward.

Disquieting news from China, where the political horizon is overcast, has aggravated the firmness of the market. Whether the Chinese position will clear without civil strife or not, the evident unrest must affect

the movements of trade, and, also to a certain extent, the means of communication, particularly the railways now occupied by military exigencies. It must not be assumed that the whole of the heavy transfers of silver in the form of specie from China to India and elsewhere, that have taken place during the period of the War, will necessarily have to be replaced at a subsequent date. Much of the silver was derived from hoards in the interior, when it has been drawn by the tempting rise in its exchange value. Moreover, substitutes have been adopted, one of which, by no means the least important, is thus indicated by the 'North China Herald' under date of April 21. 'There is another factor contributing to the depletion of silver in China, and that is, the imports of gold-bars and gold coins to China by exporters to pay for their purchases, as this way of settling bills has been found cheaper than sending the white metal here.'

On the other hand, quantities of copper cash are being smelted under private auspices in Shanghai. Such an operation was a serious crime under the Ching dynasty, and is also a punishable offence under the Republic regime. Of course a scarcity of copper cash would probably create a local demand for silver currency.

## LEAD

Lead is quoted in cents per pound, New York delivery.

The Standard Silver-Lead Mining Co. declared a quarterly dividend of \$100,000, payable July 15 to stockholders of record July 1. This disbursement will be the second of \$100,000 made this year, the first having been made on April 15. The rate of disbursement is 5% per quarter on a capitalization of \$2,000,000. The forthcoming dividend will raise the total to \$2,600,000, a greater part of which was paid at the rate of \$600,000 per year in monthly disbursements of \$50,000. The report of the company for April showed earnings of \$34,911 in that month and a surplus of \$230,420. The property is at Silverton, B. C.

## ZINC

The United States government has closed negotiations for 23,000,000 lb. of high-grade spelter at 13½c. per lb. The transaction was conducted through the spelter committee, representing zinc producers, and was the second effected in the past few weeks. When the zinc committee was formed a few weeks ago a small amount of spelter was purchased apportioned among the various grades, known in this connection as A, B, C, and D. The total approximated 4500 tons and the prices ranged according to grade.

## QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Date	4 Holiday	May 29	Average week ending
July 4	90.00	June 5	80.00

## Eastern Metal Market

New York, July 3.

Almost complete stagnation describes the market of practically all of the metals. The continued uncertainty of any decisive Government action regarding purchases and prices, that will give some idea to the trade as to what to expect for some definite and relatively lengthy period, instead of spasmodic buying for a month's needs or less, is acting as a decided drag on the market.

Copper manifests a weaker tendency and prices are nominal.

Tin is steady but inactive and dull.

Lead is unsettled and lower, with the tendency soft.

Spelter is absolutely dead and weaker.

Antimony is quiet and unchanged.

The steel market is also more or less at sea awaiting something definite as to what measures are to be taken regarding its regulation both as to prices for materials and as to taxes on excess profits. The coal fiasco has not tended to lessen anxiety. An end to the chaos is earnestly desired and absolutely necessary. Pig-iron output for June was lower than that of May because of coke-troubles. The total for June was 3,270,055 tons, or 109,002 tons per day, against 3,417,340 tons in May, or 110,238 tons per day. The output for the first half of 1917 is less than that of the first half of 1916, or 19,069,892 tons against 19,410,453 tons.

### COPPER

Daily-press reports are persistent that the Government has purchased 60,000,000 lb. of copper at 25c. per lb., the price being a tentative one subject to change later if it is decided that it is necessary as a result of Government investigations. This scale is credited by some in the trade and discredited by others. It is also rumored that a purchase of about 15,000,000 lb. is to be made at any moment. The whole matter seems to be shrouded in mystery and secrecy. It would be better for the trade in this and other metal markets if some definite conclusion could be arrived at. The entire copper market is quiet and easier, with the general tendency downward. No business is reported worth talking about outside of the Government order referred to, and the market is a drifting and nominal one, with early-delivery metal quoted at 31.75 to 32c., New York, third quarter at 30c. and fourth quarter at 29c., New York. Small lots have changed hands but quietness rules. Reports of strikes and excessive wage-demands among copper miners in the West are attracting more attention than anything else, but in some quarters these are regarded as exaggerated for political and economic effect. The London market is unchanged at £142 for spot electrolytic and £138 for futures.

### TIN

The absence of regular receipts of cables from London until late in the day, or more often until the next day, is exerting an unsettling influence. Sellers are in the dark each day as to what quotations to make, and buyers are in doubt as to what action to take. As a result business is held in check. The entire market is slow and permeated by extreme cautiousness on the part of everyone. Yesterday, July 2, no spot business was reported, but about 100 tons of futures were sold in the shape of September-October shipment from the East at 56.25c. Inquiry for June shipment from the East developed a scarcity for this position and none was to be had. The spot market came to a standstill. Last week business for any position was meager. A little spot-business was done on June 27 at 62c., New York, but on the 28th no sales were reported, though inquiry on that day and the day following was fairly good, amounting to probably 100 tons in all. There are no developments as to what the sub-committee on tin has done or is

doing, and the entire market is quiet and dull with quotations at 62c., New York, on every day since our last letter. Deliveries of tin for June, according to the New York Metal Exchange, were 6398 tons, of which 2798 tons arrived at Pacific ports. The quantity afloat July 2 was 3081 tons, with the arrivals on that day 280 tons. The London quotation for spot Straits was £244 on July 2, a decline of £1 from the previous quotation.

### LEAD

The reaction, which was forecasted last week, has developed in a mild form, and today the market is quoted at 11.25c., St. Louis, or 11.37½c., New York. It is bare of features, however, and the tendency is to lower levels if anything. More metal is being offered than the demand seems to be able to absorb, and business generally is dull and unsatisfactory. Late last week a little business was done as low as 11 to 11.25c., St. Louis, but at the close of the week better inquiry developed, and a fairly good business was reported. The sale to the Government of 8000 tons at 8c. per lb. as its July requirements, with nothing settled as to future needs and prices, has not been a stabilizing influence, and the continued uncertainty has acted as an unsettling factor. Further reaction is looked for by some.

### ZINC

Unconfirmed reports are to the effect that the Government has purchased 11,000 tons of high-grade spelter at 13.50c. per lb., St. Louis, or 2c. per lb. above the price paid for the 6700 tons bought early last May. Definite information regarding the whole question of Government needs and buying seems unobtainable, and in the meantime the market is growing weaker almost daily. The continued suspense and uncertainty is acting as a great drag on initiative and enterprise, and soon will become serious unless something is settled. One daily trade paper is responsible for the above report but no one in the trade has definite knowledge regarding it. Also it is stated that the Government has bought sheet-zinc at 16c. per lb., as compared with the present quotation of 19c. This has not been confirmed. Prices have declined recently. Early delivery of prime Western is quoted at 9c., St. Louis, with August and September metal at 9.12½c., St. Louis, but sales have been very few. It is acknowledged that many producers cannot operate at a profit at these prices and it will not be surprising if numerous small ones are obliged to shut-down before many weeks unless the situation clears decidedly. Exports of spelter in May were large—18,533 tons.

### ANTIMONY

Conditions are unchanged, and demand is light, with Chinese and Japanese grades quoted at 19 to 19.50c., duty paid, New York. A consignment of Cookson's antimony from England, the first to be released to this market in a long time, has been sunk by a submarine. It was quoted at about 22c., New York.

### ALUMINUM

Demand is not active and the market is a little easier. No. 1 virgin aluminum, 98 to 99% pure, is quoted at 58 to 60c., New York, for early delivery.

### ORES

TUNGSTEN: The ore market is quiet, with demand reported as only of moderate volume. Quotations are unchanged at \$20 to \$22 per unit for 60% concentrate. The ferro-tungsten market is also dull. Offers to sell at \$2.20 per lb. of contained tungsten have been made for export, with quotations generally varying from that to \$2.50 per pound.

ANTIMONY AND MOLYBDENUM: There have been no changes reported, and conditions and quotations are unchanged from those prevailing in last week's letter.

## Company Reports

### NORTH BUTTE MINING COMPANY

The annual report of the North Butte Mining Company for the year ended December 31, 1916, shows that during the year there was shipped 560,673 wet tons of ore and 120 wet tons of precipitate, and there was treated at the smelter 544,365 dry tons of ore and 89 dry tons of precipitate. Of this ore 49,252 dry tons, or 9.1%, was first-class, 423,118 dry tons, or 77.7%, was second-class, and 71,995 dry tons, or 13.2%, was third-class. This ore produced 24,498,181 lb. of fine copper, 1,047,063.56 oz. of silver, and 1,712,004 oz. of gold. During the months of November and December there was also mined 1652 wet tons of zinc ore and there was treated 1625 dry tons, which produced 412,953 lb. of zinc and 2510.24 oz. of silver.

Deliveries of copper, silver, gold, and zinc made during the year, in amounts and at average prices received, were as follows:

Copper, pounds .....	21,505,584	23.295c.
Silver, ounces .....	960,246.62	66.371c.
Gold, ounces .....	1,712,004	\$20.00
Zinc, pounds .....	412,953	10.674c.

Four dividends were paid during the year, as follows:

No. 37, January 26, 1916.....	\$ 215,000
No. 38, April 26, 1916.....	215,000
No. 39, July 29, 1916.....	322,500
No. 40, October 23, 1916.....	322,500

Total .....\$1,075,000

The mine was in operation 349½ days, the average number of men employed was 1160, and the average tonnage hoisted daily was 1605.

The net cost of producing copper was 15.51c. per lb. as shown in the following statement:

Classification	Cost per lb.
Mining and development work.....	\$0.108784
Freight on ore .....	0.002749
Concentrating, smelting, freight on bullion, refining and selling expenses .....	0.075352
General and miscellaneous expense, personal and federal taxes .....	0.002539
Total .....	\$0.189424
Less value of silver, gold, and zinc.....	0.033724
Net cost .....	\$0.155700

### THE BROKEN HILL PROPRIETARY COMPANY, LIMITED

The half yearly report of the Broken Hill Proprietary Company, Limited, for the year ended November 30, 1916, shows the following:

At the mine operations were carried on continuously, except on several occasions of 'stop-work' resolutions carried by the miners. Costs show a material increase, due to this cause, and to the higher cost of supplies. The quantity of ore mined was 110,276 tons. Exploration was carried on during the half-year period, but nothing of value was disclosed.

The zinc concentration plant was again operated during the last month of the half-year, and produced 2805 tons of zinc concentrate of a slightly higher grade than had been previously obtained, the average being 47.41% zinc. The installation of a slime-flotation plant was completed and operations started in the middle of the half-year. The results obtained were eminently satisfactory, a lead concentrate of about 56% lead and 80 oz. silver; and a zinc concentrate of about 46% zinc being produced.

At the Newcastle steel works a succession of strikes of workmen greatly hampered production and increased expenses, while the shipment of finished products available for delivery was seriously hampered. Since the issue of the last report the Imperial Government has completed the purchase of 30,000 tons of shell-steel, steel rails, and fish-plates. The successful issue of £400,000 of 6% debentures enabled the management to decide upon the duplication of the blast-furnace plant; and everything is being urged forward as rapidly as possible.

The gross profit for the half-year amounted to £171,598 15s. 3d., which after deducting £15,169 4s. for depreciation, leaves a net profit of £156,429 11s.3d. During the term the sum of £325,969 4s. was expended in construction, the principal item being in connection with the Newcastle steel works, which amounted to £318,732 6s.8d.

After providing for all outstanding liabilities there remain liquid assets in cash, bullion, and other convertible stocks, representing a total value of £326,322 16s.6d.

### CANADA COPPER CORPORATION, LIMITED

The annual report of the Canada Copper Corporation for the year ended December 31, 1916, shows the following:

Operations at the Greenwood smelter were continued during the year. After writing off to depreciation \$235,238.37, a profit of \$215,304.85 remained. The total amount of ore smelted during the year was 306,450 dry tons, of which 23,243 tons was custom-ore. From this was produced 5,196,239 lb. of fine copper; 49,928.71 oz. of silver, and 12,366.24 oz. of gold. It was only possible to operate the smelter profitably because of the high price of copper. High costs resulted due to the ore being taken from pillars and caved areas remaining in the mine and also to the high cost of labor and supplies. The smelting operations were interfered with, due to continuous shortage of coke, which condition still exists.

In the last annual report, reference was made to the decision to proceed with underground work at the Copper Mountain property, the purpose of which was to confirm the results previously secured from diamond-drilling. It was also planned to lay out the work as part of the permanent programme, looking to the underground development of the mine, for extraction of ore on a large scale.

In order to provide for the rapid completion of the amount of underground work planned, a power transmission-line 13.6 miles long was brought in from Princeton, B. C., where a lease upon a power-plant had been secured. Ample compressor facilities, machine, blacksmith, and carpenter-shops were installed, also warehouses, bunk-houses, and additional dwellings. Heat, light, water, sewer, and telephone-systems were also provided.

A permanent pumping plant has been installed at the river and a Gould triplex pump is operating under a head of 1700 ft. in one lift.

Since the first of the present year, a 50-ton experimental flotation mill has been placed in operation. The purpose of this plant is to outline definitely in advance the metallurgical procedure which is to be adopted in the large mill.

A tunnel 9 ft. by 9 ft. in the clear was driven 2100 ft. on the 3950-ft. level. In addition to this, numerous lateral drifts and raises were made, the total amount of driving and raising up to the end of the year amounting to 5206 ft. As soon as it became apparent that the results secured from diamond-drilling were reliable, drilling from the surface was resumed, and 8007 ft. of diamond-drilling was accomplished during the year. In addition to this 2364 ft. of surface-trenches was sunk on newly located claims.

The net cash expenditure during the year on the development of the Copper Mountain property was \$396,000. This includes payments on account of the purchase price on claims under bond as well as administrative and engineering expense.

There remains a total of \$18,000 not yet due, to complete pay-

ment for all the mining area at present desired on Copper mountain.

The development work at Copper Mountain during the year demonstrated the accuracy of estimates previously made and upon which tonnage estimates had been established.

No material increase in ore reserves can be reported because the underground work was directed along the line of diamond-drilling previously performed. However, since the beginning of the year, underground diamond-drilling was started, which work could not be undertaken until underground work had been advanced sufficiently for the purpose. New ore is being found.

Prior to the underground development campaign, it was deemed expedient to class the ore as reasonably assured and probable. It is now estimated that there are 10,000,000 tons of definitely assured ore and 2,000,000 tons of probable ore. The average grade of this tonnage is 1.74% copper and 20c. per ton recoverable in gold and silver.

The possibilities for still further increases are considered excellent, in view of the results being secured at the present time, and in view of the existing geological conditions.

Allen H. Rogers made an independent report on the properties, and his report confirms our estimates with regard to tonnage and value of ore. His conclusion is that the property is sufficiently developed to warrant the erection of a mill having a capacity of 3000 tons per day. He estimates the cost of producing copper at 9.57c. per lb., based on existing smelting contracts for the treatment of similar product elsewhere in British Columbia. A conservative figure for the cost of transportation is assumed.

#### ST. JOHN DEL REY MINING COMPANY

The 86th annual report of the St. John Del Rey Mining Co. for the year ended February 28, 1917, was submitted by the directors at a meeting held in London, June 21, and shows the following: Tons of ore hoisted, 198,586. Tons of ore crushed, in 130-stamp mill, 187,400. Recovery in gold and silver, 110-552 oz. Value realized in London, £471,247. The proportion of mineral rejected was but 2.89%. The yield per ton was 50s. 3½d. The profit for the year was £155,593 and a balance of £7574 was brought forward.

The superintendent's report states that a favorable change has taken place in the lower levels, both as regards the size of the lode and the value of the ore.

During the year the amount of new ore blocked out greatly exceeds the amount of ore extracted.

#### Nevada Section A. I. M. E.

The second annual field-meeting of the Nevada section of the American Institute of Mining Engineers was held at Ely, McGill, and Ruth, Nevada, on June 22 and 23. The meeting was highly successful and the various visiting engineers and their ladies were loud in their praises of the hospitality of the engineers of the Ely district. The first day's session was held at McGill, where 45 members from various parts of the State were present. This was a technical session; it opened with an address of welcome by C. V. Jenkins, business manager for the Nevada Consolidated Copper Co. After a response by the chairman, J. W. Hutchinson, five papers prepared by members of the Nevada Consolidated staff were read and discussed. The titles of these are:

'Present operation of steam-shovel mines'. By Robert Marsh, Jr.

'Branch-raise system at the Ruth mine'. By Walter S. Larsh.

'Ball-mill practice'. By Geo. C. Riser.

'Coarse-crushing practice'. By Curtis H. Lindley, Jr.

'Handling and roasting fine-slime concentrate at the Steptoe plant'. By R. E. H. Pomeroy, and J. C. Kinnear.

'Water supply'. By Lindsay Duncan.

An adjournment was then taken after which lunch was

served at the company mess. During the afternoon an inspection was made of the smelter, concentrator, and crushing plant of the company. In the evening a banquet was tendered to members and their ladies at the Steptoe hotel at East Ely, after which the 54 guests participated in a dance. On the following morning the party proceeded to Ruth, where many went underground in the Nevada Consolidated mine, while others inspected the operation of the churn-drills and the steam-shovels in the great pit. After a lunch served by the company, a paper was presented by Edward Steidle, engineer in charge of the U. S. Bureau of Mines Rescue-Car No. 1. An inspection was then made of the rescue-car stationed temporarily at Ruth, after which a demonstration by rescue-teams of the Nevada Consolidated Copper Co. and Giroux Consolidated Mines Co. was presented. The ladies, who on the previous day had been entertained at luncheon by Mrs. C. V. Jenkins of McGill, attended a luncheon given by Mrs. Walter Larsh of Ruth.

The officers elected for the ensuing year were R. E. H. Pomeroy of McGill, chairman; J. C. Jones of Reno, vice-chairman; Henry M. Rives of Reno, secretary-treasurer. The new executive committee, which includes the chairman and vice-chairman, consists of the following: Emmet D. Boyle, Governor of Nevada, John G. Kirchen of Reno, J. W. Hutchinson of Goldfield, C. B. Lakenan of McGill, Whitman Symmes of Virginia City, Frederick Bradshaw of Tonopah, and W. H. Blackburn of Tonopah.

In the evening, after the return from Ruth, members attended the Red Cross dance at Ely in lieu of one that had been planned for the visiting engineers and their guests.

#### Mining Decisions

##### SEVERANCE OF MINERAL RIGHTS—ADVERSE POSSESSION

One who purchases surface rights to land and then forms the intention of holding the mineral interests therein, does not establish adverse possession unless his claim is open and notorious. The mere use and possession of the surface is not enough to constitute adverse possession of the mineral rights, even if he actually mines coal for domestic purposes only, where he is entitled to mine for domestic purposes under his deed. Paying taxes on the surface raises no adverse claim to the minerals beneath it in such a case.

Pond Creek Coal Co. v. Hatfield (Kentucky), 239 Federal, 622. February 6, 1917.

##### OIL AND GAS LEASE—ONE DOLLAR CONSIDERATION SUFFICIENT

An oil and gas lease was granted upon \$1 consideration, together with a covenant on the part of the lessee to drill a test well within a year and pay royalties thereafter based on minimum rentals. Five months later, nothing having been done under the lease, the land owners declared the same void and without consideration and made new leases which were assigned to defendants. Held, on suit by the first lessee to enjoin any assertion of rights by the assignees of the second lease, that the one dollar consideration paid for the first lease was sufficient to support the same during the period in which test wells were to be bored and an injunction was awarded.

Lindlay v. Raydure (Kentucky), 239 Federal, 928. February 3, 1917.

##### ADVERSE CLAIM—ABANDONMENT

In an action brought on an adverse claim in patent proceedings, the defendant abandoned his application for patent to the area alleged to be in conflict after the suit was commenced and the plaintiff waived his right to secure patent to that area also. Held, that as the action then became merely one for possession and there being no proof of a conflict, it was an error for the court to direct a verdict for plaintiff.

Lucky Four Gold Mining Co. v. Bacon (Colorado), 163 Pacific, 862. March 5, 1917.

# INDUSTRIAL PROGRESS

## Compressed Air on a Measured-Service Basis

The Yak Mining, Milling & Tunnel Co. owns the Yak tunnel at Leadville, Colorado, and operates its own properties, leases and operates other properties adjacent to the Yak tunnel, and also sub-leases parts of the ground controlled by them to other operators. The Yak company provides practically every service and supply necessary to the sub-lessee, except labor and capital, for a reasonable charge.

The evident advantage of this service to a miner who wishes to lease is that he can operate with all the facilities and economies of large, modern mining conveniences for the gen-

THE EXCELSIOR AIROMETER

eration and distribution of power, with a well-equipped store-room at the tunnel portal, with mechanical haulage; all ready for instant service, without any outlay of capital on his part. The charges for this service are based on the actual cost of such service to the company, which expects to derive its revenue from the discovery and extraction of ore rather than to exploit the sub-lessees for the service rendered. Hugh C. Watson, superintendent of the Yak company, says of this: "One of the principal items of power-service to sub-lessees is compressed air. For many years the company sold air to those who wished to purchase it on a flat-rate. This rate was made as accurate as possible, by a comparison, made in the office, of the cost of air for a machine-shift to the company. It will be apparent that this method and basis would never be absolutely accurate.

"In the first place, it is not a simple thing to determine exactly what the air for a machine costs a company per shift without a measuring-device, because the air-drills, even when new and of the same pattern, vary considerably; because the actual running conditions are exceedingly variable; because

the foremen who collect the original data are not generally given to research work; and also, because air-leaks are distributed and charged to the drills. On the other hand, it did not seem fair to charge a lessee for a full shift of air when it is almost a certainty that at some time during the month his machine would only be in use a fraction of the shift. This brings up the question of keeping track of the drills used by the lessee. At this mine (which is so large that a personal visit every shift by a company representative was impracticable) a compromise was introduced. A lessee was charged for air each working-shift regardless of whether he used his machine or not, unless he signified his intention of not using his machine on certain shifts, in which case he was not charged for air on those shifts.

"It was decided that, if the air could be sold on a measured-service basis, it would obviate all the objections mentioned, make a fair basis of settlement, and that it would be satisfactory to all parties.

"It was also felt that the introduction of meters would effect other economies not so apparent on the surface, not large in most instances, but in the aggregate making an important saving.

"Anyone who has had any experience with lessees or contractors who buy their own supplies will testify to the tremendous saving these men make when they know that they themselves are paying for the extravagance and waste. Their economy in these matters amounts to parsimony.

"It is a well-known fact to mine operators that the ordinary mine employee considers a leak in the air-line as a small matter, rather beneficial than otherwise, and a continual fight on the part of the supervisor to stop such leaks is considered as a finicky characteristic of bosses, which occasionally degenerates into nagging.

"The next question was the cost and kind of a meter to use. Several meters for air are on the market, and at first the cost of the cheapest of these was considered prohibitive. However, the need was so urgent that this company felt that a few should be bought and installed, and then to buy the balance if the results justified the expenditure necessary.

"It may save someone considerable trouble to start in where we left off, so I will state that, after careful analysis, we found the Excelsior airometer to be accurate and not to reduce the air-pressure by its passage through it, and consequently decided to adopt the Excelsior made by the Denver Hydro Company.

"Having purchased the meters, the next question was to determine the cost of the air. This was accomplished by connecting several of the small meters in parallel and exhausting air from the compressors through these meters. The air was kept at a constant pressure during this test, and meter readings were taken from the motor which drives the compressor simultaneously with the readings of the air-meters. It was then a simple matter to factor the power, labor, and oil-costs into cents per 1000 cu. ft. of compressed air. At about the same time a meter was connected to various air-drills, under variable but ordinary conditions, for long periods, to determine the actual daily consumption of air per shift. In this way the actual air-cost per drill per day was determined. It is not claimed that this method is absolute, nor were there any hair-splitting factors introduced, the idea being to get a commercial comparative basis on which to sell air that would be reasonable and just to both sides.

"Due to the fact that the company still operates drills on its own account with no meters attached as yet, and also

because the original cost-data were inaccurate, it has not been possible to say how great the saving has been, but this much is apparent: That previously there was a scarcity of air; at present, an abundance, and this notwithstanding the fact that we are now operating four more large drills than ever before with these compressors.

"The air problem had resolved itself into selling the air at the least cost that would protect the company in its power and up-keep. This figure having been determined and the meters installed, the difference to the lessees was a general reduction of the air-bill, which immediately led some lessees to buy machines, who had previously calculated that they could not afford them, with a net result for the company that the revenue from the meters was about the same as from the flat-rate schedule. However, the big advantage came, as anticipated, from the economy and prevention of leakage.

"An incidental benefit which might be credited to these meters was the discovery that one of our compressors cost nearly twice as much per 1000 cu. ft. as another. This led to the installation of a more modern and economical compressor. This saving soon became apparent and was shown on the power-bill.

"The company keeps one meter to test the conditions of the different drills. It is known to everyone that the depreciation on an air-drill is one of the contributing factors of the high cost of mining; but unless one has a specially constructed and expensive dynamometer, it is difficult to tell when it is time to scrap old drills and buy new ones. We have adopted the following scheme:

"When the machine is new, we drill a hole at a convenient place in the mine and record the time, air, size of bit, machine, etc., then this record is filed away and later, six months or more, this same machine is again tried in the same place under similar conditions. The loss of efficiency is shown by comparing the number of inches drilled with the same amount of air and in the same time as when the machine was new. By assuming that when the drill was new it was 100% efficient, and reducing the hole drilled to a common denominator, we get a good idea of the efficiency of the same, or different machines, and also the depreciation of the different makes of drills. This method is a great help in knowing when to change drills, because the price of the drill is but a small part of the cost of the work done while labor and power are at the top of the list.

### Matteson Mine Ore-Cars

Every miner is interested in mine-cars, particularly in a common-sense serviceable car, that will stand up to the requirements of continued service without requiring the frequent attention of the blacksmith or the foundry-man. Such a car is that here illustrated. It is known as the Matteson car, and it is a car that will appeal to every miner that uses it, particularly the man who has to handle it. Its low cost of up-keep also makes it a favorite with the manager who has an eye to economy. It is supplied with a roller-bearing turn-table, making it easy to turn the body of the car in any direction when ready to dump it. The bearings of the wheels are provided with an excellent lubricating device, the axles being wholly enclosed and rolling on bearings which make running smooth, with a minimum of friction, and as grit is absolutely excluded a car after considerable use runs as easy, if not easier than a new one.

Another excellent feature is the compound hinge that controls the dumping arrangement. When the

hinge-latch is released the car-body tilts forward at an angle of 10°, so that when ready to dump the loaded car it is readily accomplished without lifting at the rear end of the car, as is commonly the case with mine cars.

The car is made in two shapes; one being the rectangular, with a nearly vertical front; the other, called the scoop car, which has the receding front, permitting the ready discharge of wet sticky rock, wet concentrate, and similar material. The car can be had with either side or end-latch, as preferred, and with either side or end-dump. The miner can select the car best suited to his requirements, as the cars are made in various sizes from 25 to 40 cu. ft. capacity. The wheels are 12-in. diameter and the car is made 18-in. gauge, though other sizes and gauges are built to order. These cars are made by the Joshua Hendy Iron Works of San Francisco. A well illustrated pamphlet, Bulletin No. 125, descriptive of this car, will be sent on application to those interested. This firm makes a specialty of many machines that are peculiarly suited to the needs of the small miner; small hoists, small stamp-mills, ball-mills, and other devices required in the early development of mines.

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.  
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bdg.; New York, 1760 Woolworth Bdg.; London, 724 Salisbury House, E.C.  
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

# Speed up with Electric Power

*G-E Equipment is reliable and economical*

**H**ERE are some of the ways in which modern industry has been speeded up by putting electric power to work in the right place.

Metal mines have boosted output to meet world-wide demands. Great central power plants in place of small local plants in coal mining areas now supply cheaper electric power per ton output for each mine. All tonnage records have been smashed in the steel industry. Greater automobile output has lowered prices and given better road transportation. More and better cloth has been produced at lower power costs.

The engineering problems solved in putting electric power to work in these and other industries were many and intricate. Production of electrical equipment suited to this work and in quantities required is an important part of this company's service to American industries.

Any problem involving the use of power can be simplified by the application of electricity. The General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to co-operate with manufacturers and engineers in every possible way.

# EDITORIAL

T. A. RICKARD, Editor

CONGRESS as yet has not taken final action to relieve locators from doing annual labor on their mining claims during the War. The Senate has agreed to the House resolution exempting those persons who may be mustered into service in the Army or Navy from the obligation of doing the statutory \$100 worth of labor, and the Senate has adopted another resolution, introduced by Mr. John F. Shafroth of Colorado, which provides for acceptance, in lieu of the required assessment work, of an equal expenditure in producing supplies needed for the support of the Army or Navy or of the people of the United States.

REACTIONS between sulphur and oil are discussed by Mr. G. Sherburne Rogers in an article appearing in this issue. The source of the sulphur is of interest to the student of ore deposits as well as to the specialist in petroleum. For the most part it is traceable to waters carrying sulphates in solution, coming under the influence of reducing substances in the sediments and in the oil itself. A point of particular significance is the statement that oil will also reduce sulphur from pyrite. This has been suggested also by investigations in connection with the flotation process, it having been claimed that this reaction may exert an influence upon the surface of sulphide mineral particles, making them more readily floatable.

ALUMINUM has been selling during the War at approximately 60 cents per pound. In June, 1914, it sold for 17.5 cents, and the upward trend, beginning in April, 1915, was like a balloon ascension. This was occasioned by its demonstrated value in the making of explosives. It is significant of the general inflation of prices, in no wise corresponding to increases in the cost of production, that Mr. Arthur V. Davis, president of the Aluminum Company of America, has offered to supply the Government with all the aluminum it needs at 27.5 cents per pound. He is said to have arrived at this figure by adding 2 cents to the average market-price of the metal during the past decade. Mr. Davis deserves commendation for the merit of frankness in revealing one more truth regarding costs of production.

OUR Toronto correspondent, in last week's issue, records a judicial decision giving damages to residents in the Sudbury district for injury done by smelter-fume, but refusing to grant an injunction against the two smelting companies in that famous nickel-mining district because the Court was of the opinion that "in-

dividual rights could not be maintained against the interests of the whole community." The Court refused to destroy the local mining industry even to save a few farms. This seems just and for the public good. The smelting companies have expressed willingness to buy at a liberal price the lands of those that claim to be suffering from the effect of the smelter-smoke. It is time that the public showed resentment against the blackmailing of a basic industry, the industry that in many localities was the chief cause in giving a value to the farm-products by affording employment, and therefore buying-power, to the local population.

SILVER is selling for 81 cents, a price not quoted since 1892. The reasons for the rise have been stated in these columns on several occasions: first, they are the increased purchasing power of China and India, both of which produce commodities that have been in steadily growing demand and for which, according to their custom, they ask silver in exchange; second, the coinage of silver for the use of the armies in Europe, particularly those of Great Britain, France, and Russia. To these now must be added the United States; for it is the purchase of silver by our Government that is the proximate cause of the recent rise. San Francisco has become the principal point of export for silver, instead of New York. The Mexican, Canadian, and American production goes this way to the Far East, in order to avoid the submarine menace in the Mediterranean. London still fixes the price of silver, because business there opens five hours earlier than at New York. The improved prospect for the metal should not only benefit Tonopah and Cobalt, the two chief silver-mining districts in northern America, but it should swell the profits of the copper-mining companies, many of which, particularly in Montana, recover silver as a by-product. Another consequence is to help Mexican finance, for the peso is appreciating rapidly. The rise may also put it into the head of the Mexicans to assist and stimulate the mining of silver ore instead of looting right and left. A revival of silver mining in Mexico would help greatly to extricate that country from its difficulties.

MEETINGS of scientific societies have been discouraged by the leaders of a number of these organizations on account of the War. The American Electrochemical Society, however, has vigorously opposed such a policy, and we agree that the helpfulness of personal contact, the inspiration gained through an exchange of thought between the men who are doing the world's work,

and the dissemination of practical knowledge that is elicited in discussion, should not be sacrificed at a time when the country needs more abundantly than ever the advantage of these quickening influences that develop proficiency and stimulate inventive ability. Under the stress of these abnormal times, we are learning the high patriotism that resides in work for the common welfare, and gatherings of scientific men will assume a new importance. The banquet and the oratory will be subordinated to more serious things. Never were conferences of technical men more justifiable than at the present moment, when exchange of information is urgently needed. This is the basis of intelligent co-operative effort, and we may add that the spirit of solidarity should reach further. The tendency to erect a medieval wall of secrecy around many metallurgical and chemical works, that has grown more pronounced in recent years, is distinctly opposed to progress. The open door to men of appreciation and understanding brings its reward through enlightening criticism and suggestion. The example set by Dr. James Douglas, who extended a cordial welcome to every intelligent visitor at a time when a contrary custom almost universally prevailed, is worthy of emulation; his policy of free-trade in technical ideas did not hinder the economic development of the Phelps-Dodge industries. A similar policy will help all America in the winning of this War.

LAST week our Leadville correspondent sent a most interesting account of the hearing given by the State Industrial Commission in Colorado to an argument made by representatives of the local union when demanding higher wages. The Commission found that the cost of living had not risen as much as claimed, that the operators do not receive anything like the full benefit of the increase in metal-prices, and that the margin of profit is so narrow that any considerable increase of cost would jeopardize local industry. This reminds us that the legislature of Colorado at its last session appointed a Smelter and Ore Sales Investigation Committee. This committee was ordered to investigate the smelting business and report to the Public Utilities Commission before January 1, 1918. The committee of investigation is described by mining engineers in Colorado as "pretty good," which means above the average. The members of the committee are all men well informed in mining affairs and likely to make an intelligent enquiry. They have been authorized to investigate all custom-mills, smelters, and sampling-works; also to ascertain whether the customers receive weights, moisture-deductions, samples of ore, and assays; also to find out whether proper prices are paid for copper, lead, and zinc. For instance, they are expected to be curious concerning the payment by the American Smelting & Refining Company of 4½ cents per pound for lead when the market-price stands at 10 cents. They have been requested to make recommendations for correcting any wrongs they may detect, and if they do this, it is expected that they will suggest the placing of custom-mills and smelters under the Pub-

lic Utilities Commission of Colorado, after submitting the proposal to public vote on a constitutional amendment. The investigation is backed by the Metal Miners Association of the State. We understand that the dominant smelting company has already made sundry concessions, and we are informed that the most unscrupulous of the Denver papers—it is not necessary to specify further—has already attempted to blackmail Mr. Simon Guggenheim. The report of the Committee is awaited with keen interest.

DURING the past week the I. W. W. movement has gone through a serio-comic phase. It may seem comical for the outraged citizens of a mining community to take the law into their hands, herd a lot of anarchists and loafers into an enclosure, and then ship them on a train to some distant point, 'passing the buck' to another community, preferably a neighboring State. It is a serious matter when citizens, in order to assert law and order, at a time when the naval and military forces of our country are fighting to "make the world safe for democracy," feel compelled to stultify government of the people by arming themselves and using force to eject an undesirable element from their midst. Viewed from any standpoint it is deeply regrettable that matters should have come to such a pass, and somebody is to blame for it. The only good that has resulted is the opening of the eyes of the public to the seriousness of the crisis and possibly to some realization of the forces of misrule set in motion by this organization of men unwilling to work and unwilling to let others work. The argument based on the high cost of living and the rest of it has been exposed as a mere pretense. They want the three sixes, namely, \$6 wages, six hours of work, six days per week, and when they have obtained that they will demand \$7 wages, five hours work, and a five-day week. Even this will not be the limit. No thoughtful observer of the conditions obtaining in the mining communities of the West at the moment can any longer regard the excuse for strikes as founded on the reasonable aspirations of honest labor. Whether financed by German money or stimulated by Enemy propaganda, or not, the whole campaign of these I. W. W. agitators is calculated to give aid and comfort to the Enemy, and therefore it is treasonable, not to be endured, and calling for prompt action by the executive. Much of the trouble, as usual, is due to politics. During the week the disturbance has spread beyond the immediate vicinity of the mines. Even around our own academic environs, at Berkeley, we read that "to prevent the threatened I. W. W. invasion of this county, the sheriff has stationed deputies upon all the roads leading from Contra Costa county," because "the I. W. Ws. have threatened to burn the county's grain supply." Things have come to a pretty pass when we are menaced by a Boxer rebellion or a Villa raid, as it were, in the heart of an orderly community. We are engaged in a great war; it is time to put a summary end to these antics and assert the dignity of this democracy.

## The Mexican Menace Again

Our Mexican correspondent this week calls attention to new regulations affecting the producers of oil that would be confiscatory, unless we and our Allies oppose the taking of their property by administrative process. The present situation is not by any means new; we have been pointing out for months what was coming, and it is possible that the Department of State has not been idle. Not long ago Senator Frank B. Kellogg, at a hearing before the Public Lands Committee on sources of oil, asked if we might depend upon Mexico for this important necessary, and Commander James Richardson responded in the way of the man whose business it is to win a fight when he has gone into it, "Don't you believe that if it depended on getting oil from Mexico we'd get it, even if we had to take Mexico to do it"? It is this sort of straightforward talk that has helped to bring clearly to the mind of Carranza the expediency of trying to make a virtue of necessity. The peculiarity of the Carranza mind is that it is essentially subtle, and, just as he has done so often in his revolutionary career, he is now resorting to clever diplomacy and to what might be called the strategy of statecraft to wring success out of failure. We confess to no little admiration for the astuteness of this Mexican fox; if we cannot comprehend his moves and circumvent them we deserve to be beaten at the game, and to accept the fate of the geese.

The operators in the Mexican oilfields fully understand what they are contending against; they have perceived it ever since the new constitution made at Querétaro declared the nationalization of the oil-lands. To put oil on the same footing as gold, silver, copper, and lead was to recognize the ancient right of the sovereign state in mineral resources, and to give to anyone the privilege of entering upon land, wherever held, to explore for oil, and, when found, to 'denounce' it according to the prescriptions of the mining law. In due course a leasehold title would issue. The plain intent of the constitution was to make this retroactive, the civil code to the contrary notwithstanding, since this was in line with uniformity of procedure in departmental control of oil-production, and theoretically it should work no legal hardship upon the present holders of oil-land leases; it would merely necessitate their repairing to the local mining agent to file their applications for so-called mining titles. Of course, it would mean that enormous sums would have to be paid immediately into the Government coffers in the form of fees accompanying the denouncements; Mexican surveyors would be given abundant employment in delimiting the claims in accord with the mining statute, and later in proving the monumenting of these areas. Even in normal times this always has been a heavy expense, and one can imagine what it would entail in times such as those brought about in Mexico through the turmoil of revolution, with the starvation produced through cessation of industrial activity, ending in the supremacy of a clique that knows it cannot last long and must fatten while it has the chance. Moreover,

the new system subjects the oil-claims to taxation under mining laws that have been seriously impaired by decrees issued by the First Chief before he made himself president. These not only have increased the taxes but have made them cumulative proportionately with an increase in area. It would be well for anyone having business in Mexico, whether in oil or in other enterprises, to acquaint himself with these dictatorial decrees. They may be had in Spanish and English in bound form, indexed with reference to the subjects treated. In no other way is it possible to ascertain what Mexican law is at the present moment. The decrees will show at least the situation at the time this publication was issued; by acts of the Mexican Congress the Department of Hacienda is empowered with extraordinary functions, which are legislative as well as administrative, so that decrees are still coming forward and the status of any industry may be seriously altered over-night.

The foregoing is an example of the utter disregard of titles to real property that exists in Mexico; the whole foundation of industry is unsettled by it. In the case of the owners of oil property, it is clear that there would be many a slip in the routine of putting their applications for leaseholds through to what the Mexican calls a *titulo*; something is sure to go wrong in the process of *tramitacion*, that is, in the wearisome bureaucratic red-tape leading at last to the signature, alongside the seal and blue ribbon, by the departmental head. In the discovery of technical error in legal proceedings the Mexican is a past-master. The door is thereby opened for infinite graft, for burdensome fines, and for wholesale confiscations accomplished through officially declaring applications invalid. It is hardly to be supposed that the original applicant would have time to correct his denouncement to the satisfaction of the highly discriminating officer before an application by favored competitors, under effective protection of scheming bureaucrats, would be filed with the mining agent. In our comments upon the new constitution prepared by Carranza we showed months ago what the effect would be upon the oil industry. The nationalization of the oil-lands was arranged in order to carry out the game that is now being played openly. The interference with mining companies, as detailed in our editorial pages last week, was merely a part of the same programme, intended to bring Mexican affairs prominently before the people of this country so as to increase our anxiety in preparation of the public for the next move. What this is now appears through the fact that Carranza, who has long been hinting at financial assistance from American bankers, has recently secured from his congress authorization for bond issues amounting to ₱300,000,000. With this authorization he is ready to offer exemptions from interference with mining and oil companies, and to assume the rôle of a defender of foreign interests in his country. Dispatches from Washington since the arrival there of Mr. Henry P. Fletcher show that our diplomatic representative has not been asleep. Mr. Fletcher has sounded a warning against the intentions of the Carranza govern-

ment, definitely affirming that its purpose is the confiscation of the oil-lands. If we concede the demand for a loan we shall be obliged to pay the bills for running the Mexican government as a private monopoly of Carranza and his followers throughout the War. We may be forced to undertake the operation of the Mexican republic on the side, but, if we do, it will not be in the way that Carranza has conceived. We shall run it as a real democracy for the welfare of the Mexican people, not for a clique of grafters.

## The Physics of Flotation

During the recent trial at Butte, Mr. Wilder D. Bancroft was asked, "Is that a book to which you would refer as an authority?" "Oh, dear no," he retorted; "I would not refer to any book as authority." It is not clear whether Dr. Bancroft assumed, quite properly, that he was better informed on the matter than any book extant or whether he meant that no book on a subject so obscure could be authoritative. We have read the evidence given by him and his talented colleagues in the latest litigation over flotation patents, and we acknowledge the value of their contribution to current knowledge; and yet it must be confessed that the physics of flotation still lacks scientific elucidation. We are nearer the truth, undoubtedly, for several truths have been elucidated by experiment and induction, but we have not arrived at a coherent hypothesis. By 'we', of course, we mean the whole body of earnest enquirers. Some fallacies have been exposed. That is so much to the good. The 'critical point' has been thrown into the limbo of false assumptions; the electro-static theory has slunk into the dark; the adhesion of air to metallic surfaces has been retired into the background; but who can tell us what is 'oil', that is, what is the characteristic of the oil that causes it to function favorably in flotation? The answer is coming, for metallurgic froth is being made by substances that are not 'oil'. Who can define 'metallic' lustre, not in the terms of mineralogy, but in the language of the froth-maker? What is the molecular arrangement in a surface capable of absorbing oil or in the substance that functions as oil? What is 'emulsification'? We confess to being among those that only put faith in scientific men that can define in simple terms; we do not believe that an archdeacon is defined when he is said to be a man that performs archidiaconal functions. That leaves us as we were—or slightly worse. One good sign, however, we detect, and that is the growing interest of engineers and metallurgists in the physics of flotation. Some there are that assume a supercilious attitude toward simple experiments and a top-lofty pose toward pure science in general, but they are unimportant. Mining departments still undertake to teach flotation without the aid of the department of physics, and metallurgists are half-ashamed to ask elementary questions at the door of the professor of physics, but even some of this shamefacedness is becoming changed by the spirit of co-operation, without which no man can accom-

plish anything worth while in this world. Much remains to be done. We urge teachers in mining-schools not to waste time in trying to study flotation without the guidance of those versed in modern physics. More particularly we advise those interested in the technique of the process to make the simple experiments that illustrate fundamental principles. If two or more men will make an experiment, and then discuss it, they will find how often they fail to see similarly, and how different may be the ideas suggested by their observations. From such experiments may come a clarifying discussion and the stimulation of scientific curiosity. In a branch of metallurgy in which theory is so hazy it is of the utmost importance to lay firm hands on a few facts, and that can be done best by making experiments. Consider, for example, how long Messrs. Sulman, Picard, and Nutter were able to bluff the profession with their statement that there resided a mysterious quality in a given ratio of oil and, what is more absurd, in a ratio that was proportioned to the 'ore', whereas the essence of the process was the differentiation of the constituents of the ore, the separating effect upon the mineral and the gangue. For 12 years this unscientific assertion remained unmasked; it was not until the early months of this year, after the Supreme Court had been misled into endorsing the absurd dictum, that several plants were operated under conditions that finally smothered the 'critical point' in oil, and ridicule. Remember how we were told that a certain patent, or the method supposed to be described in that patent, produced a thick, coherent, and persistent froth, so sustaining that a shovel could rest upon it, whereas other froths were so thin, flimsy, and evanescent that a match-stick would sink in them. We were told, by the Minerals Separation people, that their miraculous kind of froth was the only one that would float mineral successfully and that it could only be made by aid of a special kind of particularly violent agitation. Many believed it because few tested the assertion by experiment. Look at the fable of the greased needle. It was one of the amusing contradictions at which our childish imaginations boggled. The experiment was held to typify the flotation of mineral by aid of oil, until somebody showed that the ungreased needle likewise floated. It only remained for some iconoclast to prove that the making of a soap-bubble by a boy was due, not to the lowering of the surface-tension of the water, but to viscosity caused by the insoluble matter of the soap, or by something equally alien to drawing-room philosophy! Indeed, something of the kind did happen. Among the papers read at the Arizona meeting of the American Institute of Mining Engineers, a meeting that was in effect a symposium in flotation, there was one by Messrs. A. F. Taggart and F. E. Beach, called 'An Explanation of the Flotation Process'. This paper was written by two professors in Yale University, it discussed the principles of flotation, and it stated, among other things, that "water displaces air more readily on an oiled solid surface than on a clean surface of the same solid." The subversive statement was fortified by the description of an experiment with an

aluminum ring, which sank when oiled, but floated when unoiled. This, of course, was rank heresy. Given forth at that meeting of enthusiastic votaries of the new process of flotation, it was like rushing into a tea-party and shouting that muffins predisposed one to measles. Nevertheless, the thoughtful statement of two undoubtedly clever scientific men was allowed to pass without comment or criticism. In vain do we search in the record of the discussion at Globe for any reference to this paper. It could not be for lack of respect for the authors of it nor for want of interest in their opinions. We venture to say that the failure to refute what seemed an error was due to the insecure foundation on which the theory of flotation rested and the unwillingness of mill-men and metallurgists to venture a rebuttal. The failure to confirm or to disprove so momentous an assertion as this—that a metallic surface is more readily wetted when oiled and that presumably a metallic mineral is less floatable when oiled than when unoiled—is a reflection upon the Institute. It illustrates how easy it is to fill bulletins and volumes with reading-matter, and how difficult it is to obtain real criticism, without which we only swamp ourselves with a undigested mass of material—as if a haystack fell upon us. We have made experiments to test the extremely interesting statement of Messrs. Taggart and Beach, and we think these gentlemen wrong, if we interpret them correctly, but the point is that every student of the subject that has read their paper should be able by this time to express his own opinion upon their statement regarding the effect of oil. If we do not know what that effect is, we are astray on one of the elementary, although possibly not fundamental, explanations of flotation. So we say that the understanding of the process, and the further understanding of the physics of it, must depend upon intelligent experimentation and the scientific discussion that will ensue, and, above all, frank criticism.

## Misfires

The proper manner of loading a hole for blasting would seem to be a simple matter, but the numerous articles and letters that have been published in the MINING AND SCIENTIFIC PRESS during the last six months indicate a wide variety of opinion. The object universally sought is efficiency with safety, and that is attainable through practice conforming to the lessons of experience. It is important to note that valuable experience in blasting comes not alone from the daily work of the miner, but is derived equally from the elaborate tests made by manufacturers of explosive materials. The sum of all these observations, critically examined and sifted by trained technologists, has resulted in the development of a body of rules that may be accepted as authoritative. The wrong way of using explosives is more general than the right way, and faulty custom is difficult to correct because of prejudices held by the miners. Accustomed as so many of them are to wrong methods of charging holes, they resent attempts

by their foremen to shake them from familiar habit. The manager of a mine, however, is entrusted with responsibility for securing an economic result. He cannot concede free rein to his workmen in using or misusing materials according to their whim. A misfire represents not only a waste of explosive, but loss of time on the part of employees in searching for the unexploded charge or in digging it out; the cost of drilling the missed hole has been thrown away; and the ground broken per pound of powder on that shift is less. That is not the whole of the indictment. The majority of misfires are the result of methods in themselves opposed to the most economical use of explosives. Errors culminating in a misfire involve a loss in efficiency distributed through the entire round of shots. Under the best management scrupulous attention is given to the proper use of explosives, and the tonnage of ore and waste-rock broken per pound of powder and per foot of fuse are subjects of daily record.

Mr. E. F. Brooks rightly insisted on the use of high-force caps. He recommends 5X and 6X. His method of inserting the cap into the primer is similar to one suggested by the Bureau of Mines, punching a diagonal hole with a stick near the end of the cartridge; but he advises loading another stick of powder on top of the primer. Mr. W. S. Weeks criticizes this practice, as does Mr. Edward Higgins, adhering to another recommendation by the Bureau of Mines, with which apparently all powder manufacturers are in agreement, that is, to place the cap centrally in the end of the last stick in the hole, tying the paper of the cartridge-end around the fuse. As expressed by Mr. Weeks, the cap should point in the direction in which the wave of detonation is to be propagated. That accords with the principles governing the detonation of high explosives, as demonstrated experimentally by Bertholet. The explosion of a charge of dynamite or blasting gelatine, though it may seem to be instantaneous, is not so in reality. A measurable time-interval elapses in the transmission of the wave from its initial point to the end of the charge; moreover, the wave progresses in the direction of the initial impulse; it does not expand uniformly in all directions from the place of origin. Unlike the spherical waves of compression generated by an earthquake shock, it is rectilinear in its motion. The fulminate is exploded by the fire spitting from the end of the fuse, that is, by an incandescent spark. The heat dissociates that part of the fulminate with which the fire comes into contact, generating still more intense heat by the highly exothermic reaction; the explosion proceeds through the train of sensitive molecules with increasing velocity to the bottom of the charge, from which a blow of enormous intensity is delivered in the direction of propagation. This is easily demonstrated by the familiar experiment of placing a cap, with fuse attached, in a hole bored through a block of one-inch plank, set upon a sheet of mild steel. On exploding, the cap will punch a hole through the steel without doing serious injury to the wooden block.

The velocity of the initial impulse determines the

velocity of the detonating wave transmitted through the charge of powder. The heat generated, and the expansive effort of the confined gases that develop the explosive energy, merely react upon any part of the powder lying out of the path of progression of the detonating wave. The result is an explosion of a lower order for that residual portion of the charge. The degree of explosion depends on the velocity of the wave, and the velocity of the wave that causes detonation of the explosive lying in the path of propagation is not transmitted to the powder behind the cap. The expansive effort, on which the explosive effect depends, is directly due to the velocity of the chemical reaction, and any portion of a charge that explodes with less rapidity than the rest fails to deliver its full quota of potential energy in the form of useful work. It is apparent, therefore, that the proper place for the cap is at the end of the last stick of powder, otherwise called the primer. It is also certain that to place it elsewhere is to waste the powder.

Our correspondents display a variety of opinion regarding the likelihood of 'side-spitting' from fuse when bent. The fact that it does not happen in the majority of cases when fuse is subjected to severe handling merely argues for the excellence of its manufacture. If all articles in common use were as honestly made as explosive materials the world might draw moral inspiration from commerce. Although "the function of an explosive is to explode," as was laconically stated by Lient. Walker of the United States Navy, the extreme care taken by the manufacturers to afford an ample margin of safety against the vicissitudes of handling such delicately balanced agents of destruction, permits rougher usage than intelligent caution might commend. Mr. Higgins points out that the practice of inserting the cap in the wrong end of the cartridge, and doubling back the fuse, is the fertile cause of misfires, and misfires are responsible for one-fourth of the fatalities overtaking those engaged in mining within the State of California, which State does not stand alone in this respect. Fuse not infrequently does spit fire through the walls; seldom will a coil cut into 3-ft. lengths, and tested, fail to yield one example of this defect. That should be sufficient warrant for taking pains to avoid any chance of accident arising from this source. The advice of manufacturers is so to load a hole that the fuse may not come into contact with the powder. The fuse should be dry, as our correspondents insist; it should be cut with a sharp clean knife, never with the scissors-type of cutter often combined with a crimper, because the fuse becomes pinched, shutting off the powder-train and causing a side-spit near the end that may fail to explode the cap; the cut should be square across the fuse; the cap should be placed upon the fuse, preferably holding the latter upward and drawing the inverted cap down upon it. Just as the housewife will explain the difference in efficiency between threading a needle and 'needling' the thread, so is there a difference, tending to security and efficiency, between 'fusing' a cap, and 'capping' a fuse. The double crimp is preferable; it insures holding the

fuse in firm contact with the fulminate in the cap. The man who bites the cap upon the fuse deserves to lose his lower jaw, as he frequently does.

We venture to say that any mine breaking as much as 100 tons per ~~them~~ of ore and rock will find it economical to employ a man to make primers, and distribute all explosives to the miners. In no other way can the proper making and use of primers be insured. The 'powder monkey,' as this employee is generally called, can be trained to observe all the proprieties in making reliable primers, and in tracing the inefficient use of blasting materials if he be given responsibility as powder-foreman. It then becomes possible also to make primers of powder containing a larger proportion of nitro-glycerine, which insures a higher order of detonation, developing increased useful effort in the lower-grade powder used in regular blasting. Primers of 60% dynamite, three inches long, with 6X caps, will be found to effect a saving in powder per unit of rock broken. The wooden borer with a shoulder to limit the depth of hole for the cap, not only protects against premature ignition of the charge by side-spitting from the fuse, but it prevents an air-space being left beneath the cap. Insignificant as it may appear, the tiny air-cell left under a cap when a pointed object is used to make the hole reduces the initial force of the explosion by reason of the compression of that air before it can transmit the detonating wave. It reduces the velocity and the order of detonation, which means loss of power, waste of powder, less ore produced per pound of dynamite.

Tamping opens another interesting question, where room for argument may exist. The suddenness of detonation of a high explosive develops almost instantaneously an enormous expansive effort. On account of its suddenness the maximum resistance of the air due to its inertia is supposed to be realized. With unabsorbed nitro-glycerine this result is approximately obtained, especially when the superficial area of the explosive exposed to the air is considerable. The case is different with practical blasting-powders; their velocity of detonation is highly modified by the absorbent. Moreover the projection of a slender column of air into the surrounding atmosphere introduces new physical conditions; the power required to impel a jet is different from that required to overcome the inertia of the air surrounding a 'sand-blast' in bulldozing. Plastic tamping is first compressed and tightened in the hole; then the friction developed between the tamping and the wall, under the enormous suddenly applied pressure due to the detonation, makes the stemming almost as resistant as the solid rock.

The proper application of explosives deserves consideration by all thoughtful engineers. It is a fruitful subject for discussion, having to do with the protection of human life against carelessness and ignorance as well as touching, at so many points, the commercial result of the complex operations of mining that finally are centred upon the relation between the cost of the ore broken and the price obtained for it.

THE BUTTE &amp; SUPERIOR MINE AND MILL

## Butte Re-Visited

By ROBERT E. BRINSMADE

When I landed in Butte recently, there had elapsed just 16 years since my last sight of the city. The train that brought me, the Columbian express of the Chicago, Milwaukee & St. Paul system, with its steel cars and its electric locomotives, was an indication of the engineering progress that the interval had produced, a record of achievement in transportation that the mining industry of the locality might find difficulty in matching.

In the business district around Main street and Broadway, skyscrapers have arisen to keep company with the solitary Hennessy block of former days. The luxurious post-office, the regal county courthouse, occupying nearly a whole square, the Silverbow Club with its tasteful façade, as well as new hotels and apartment-houses, indicate that builders have become hopeful of the future of Butte and are staking their fortunes with the belief that its stability as a centre of population is assured, whatever may be the ultimate fate of its mineral resources. Indeed, the change from the Helena to the Butte branch railway for the passage of the main-line traffic of the Northern Pacific system, and its selection, in spite of the difficult topography, as the route of the new Chicago, Milwaukee & St. Paul extension to the coast, demonstrate that the city has finally shed the swaddling clothes of a transient mining settlement.

On entering Butte from the south-west, no vestiges are visible of the old Colorado smelting works, while the adjoining plant, the Butte Reduction Works, remains only as a cold and lifeless reminder of its erstwhile productivity. Farther south, the Flat, formerly so bare and forsaken, is becoming populous as a residence section, and the same may be said of Silverbow valley on the east,

where, in place of the three smelters, the Montana Ore Purchasing, the Butte & Boston, and that famous belcher of pungent sulphur-smoke, the Parrot, there functions only the infant plant of the East Butte company. Not only have the buildings and machinery of the famous old smelters been removed, but what still remains of their tailing and slag-piles is being shipped away so rapidly for re-treatment during the present bonanza era that any future delvers in the 'ruins of ancient Butte' will find few clues to the activities of former inhabitants.

The Anaconda and St. Lawrence mines, as well as adjoining shafts of the 'richest hill in the world', covering the Anaconda lode-system, seem to have changed little in superficial appearance. The existing steel head-frames had all been erected in 1900, and many of the adjoining long lines of iron boiler-stacks are still standing. Though the mines have drawn electric current from Great Falls and other Montana water-powers, the old boilers, when hardly worth moving elsewhere, form a valuable reserve in case of line-troubles. To the north, at the High Ore shaft, have been erected the great buildings that house the mighty electric compressors, which supply air to the re-constructed steam-hoists of the deep shafts of the Anaconda company. On Syndicate hill, farther west, the old land-marks, the Bell, the Diamond, the Green Mountain, the Mountain Con., and the Coulin mines, are still active, and have been supplemented by the great new Beaver State mine. This last is a visible evidence of the extension of the copper zone, which formerly was thought to be as contracted as the throat of a sperm-whale. It has now been followed to the North Butte, the Butte-Ballaklava, the Tuolumne, the Tropic

and the East Butte on the north and east, and to the Butte-Duluth, the Bullwhacker, and the Davis-Daly on the south. In 1900 the Silver Bow No. 3 vein was believed to be the southern, and the Continental fault the eastern boundary, of the copper-zone, even though Heinze had already begun to work east of Columbia Garden in what later became the productive Receiver mine. Thus the work of the past decade has demonstrated the fallacy of such a belief. Boring through the sediments of the Flat into bedrock has demonstrated the presence of copper veins far to the south, and such productive mines as the Bullwhacker and the Butte-Duluth have proved the presence of abundant copper to the east of the Continental fault. These discoveries caused a boom in the corresponding mineral rights, so that owners of town lots around the Race Track on the Flat found themselves in clover, and the claim-owners near Columbia Garden unloaded their undeveloped holdings upon the North Butte company for over a million dollars.

Even as late as 1906, the Butte report of the U. S. Geological Survey affirmed the non-existence of commercial oxidized copper ore in Butte, and the dictum was then well founded, for the outcrops of the marvelous veins of Anaconda hill, with their hungry iron-stained quartz, show less signs of the red metal than a German kitchen in war-time, and even the copper-stained Syndicate outcrops farther north have scarcely any ore of value till the sulphide-zone is reached. Yet the opening of the great granite stockworks of 5% oxidized copper ore in the Bullwhacker and Butte-Duluth have discredited the former dogma and have brought to light the belt of oxidized ore that lies east of the Continental fault, and extends south from Park canyon for more than a mile. The oxidized veins are sub-vertical and mainly contain chrysocolla and malachite, both in the veins proper and in the disseminations of their granite walls. They have been mined open-cast, by Lake Superior methods, and treated by leaching with sulphuric acid in the Butte-Duluth mill of Captain Wolvin, at the rate of 500 tons daily. Their oxidized filling extends to water-level, which is at 300 ft. in the Butte-Duluth, and then merges into the typical Butte copper sulphides; in fact, these distant veins have the easterly strike of the great veins of Anaconda hill. It appears plausible to believe that the oxidized-copper zone depends on the Continental fault, which, being 200 to 1000 ft. wide, and with a vertical throw of 1500 ft., has generated quite different conditions for surficial leaching between its opposite sides.

The saying that 'Fools rush in where angels fear to tread' has perhaps never had a more unexpected and happier outcome than in the recent history of Butte; the two 'fools' in this case being Ralph Baggaley and Captain Wolvin. The first, a Pittsburg steel-man, and consequently a novice in copper, was so ignorant as to insist that copper matte could be blown in basic-lined concentrators. Backing his belief with his large fortune, he conducted costly experiments, and finally had the satisfaction of accomplishing the impossible and of proving himself

less a fool than his critics. Captain Wolvin had gained title and fortune as a ship-owner at Duluth; so, a decade ago, when he entered the race for mining honors at Butte, he was booked by the wise-acres far down on the list of 'rank outsiders'; but the Captain, undaunted by scoffers, took hold of the old Black Rock silver mine, organized the Butte & Superior Copper Co., and proceeded to sink for another copper bonanza. Though a fool's luck did not give Wolvin a copper mine, it soon handed him a body of zinc that has out-classed in value half the copper bonanzas of the world. After the completion of a concentration mill and the flooding of the Kansas smelters with its output, he found himself able to sell his interest for a million profit, and he then embarked as boldly, but with less financial success, in the opening of the Butte-Duluth mine. The new owners of the Butte & Superior omitted last April the word 'copper' from their company's name; evidently they were too profitably united to Dame Zinc to desire further flirtations with Mistress Copper. Yet Captain Wolvin was not 'going it blind' at the Black Rock. The astute Heinze had, as early as 1902, found rich zinc ore beneath the silver-manganese ore of the old Lexington mine, and this discovery established the probable existence of zinc at depth in all the silver mines of the Rainbow lode-system extending eastward from the Amy and Alice mines to the Continental fault. The huge chimney of zinc ore, 300 ft. wide, that is now supplying the 2000-ton mill at the Black Rock mine seems to have been formed by the step-faulting of a very wide vein, and is thus not essentially different in structure from the step-fault chimneys of the Anaconda lode-system, as seen in the West Colusa or Minnie Healy mines.

The Black Rock zinc ore is a mixture of sphalerite, galena, pyrite, and quartz. As sent to the mill, it assays about 16% zinc, 2% lead, and 12 oz. silver, and produces 25% of its weight as a concentrate with 56% zinc, besides yielding a little high-grade galena. Since the adaptation to this ore of the Hyde flotation process, and the consequent saving of over 90% of the zinc, the Butte zinc-belt has attracted more attention than the copper, because less explored and therefore of more romantic possibilities. When former Senator Clark, with his usual luck, found himself owning the western extension of the Black Rock vein, in his Elm Orlu ground, he proceeded to explore his bonanza, and later built the Timber Butte 500-ton flotation-mill that is now in operation on the first hill-slope south of the Flat.

The greatest ultimate beneficiary of the pioneer work of Heinze and Wolvin may prove to be the Anaconda Copper Mining Co., which seems destined to be as important in the world of zinc as it has been for three decades in that of copper. Not only has Anaconda long controlled such famous mines of the Rainbow lode-system as the Alice and the Lexington, but it has lately acquired the Nettie silver mine, west of the Big Butte intrusion of rhyolite, and the Emma, south-west of town. In all of these Anaconda has developed zinc orebodies, and soon this company's new electrolytic zinc works at Great Falls, producing 100 tons of spelter daily, will depend on their

output of ore; in fact, Butte bids fair to possess enough natural resources to make her for an indefinite time a rival, as a zinc-producer, of the famous Broken Hill lode in Australia.

Though development has shown that the silver veins change in depth to zinc, the hypothesis that the zinc ore

and their middle zinc zone. This corrosion would result in their existing apices still persisting in the copper zones. If such be the fact, a prolonged span of life for Butte as the world's leading copper district is well assured.

Underground, Butte adhered steadfastly to square-set stoping until 1916. The original excuses for adopting

AT THE COLLAR OF THE SHAFT

changes in turn to copper is not yet fully demonstrated. The fact noted by Sales\* that the great copper veins of Anaconda hill contain less copper and more zinc as one recedes from the central copper belt does not nullify this hypothesis. The Gagnon, the Beaver State, and the Speculator furnish good examples of zinc changing to copper in depth, and there are said to be similar indications in some of the new zinc mines. It may be that the copper belt merely comprises those veins that have been the most corroded and that have thus lost their upper silver zone

this expensive practice were the cheap timber of western Montana and the ready adaptation of this system to the huge soft irregular orebodies with their resemblance to those of the Comstock lode, whence came many of the early Butte miners. Timber is now growing scarcer, and even the general introduction of the old Gagnon scheme of using round, instead of square, timbers for the sets, has given little relief, in view of the doubled output of ore; but, owing to the presence of many valuable surface-structures, any timberless system of mining that involves caving the surface is not permissible. At present the

\*Trans. A. I. M. E., Vol. XLVI, p. 3.

Anaconda company is employing a sort of 'rill system' in some of the veins that are not over three sets wide, such as the Beaver State. Levels are spaced 200 ft. apart and then connected by three-compartment raises, 50 to 100 ft. apart, timbered with square sets. The central compartment of each raise is a man-way, one side-compartment being used for sending out broken ore and the other for admitting waste intended for filling. Stopping starts at the first floor of a waste-compartment by slicing the back on an incline of 30° along the vein, that being about the angle of repose for broken rock. The back is drilled by Rand-stoppers, and the ore is broken down and dropped through the plank-lagging into cars on the drift below. The excavated space is then filled with waste dropped down the raise from the level above, and is then covered with plank, spread on its angle of repose, and with enough space between plank and back to permit the miners to drill the vein for another slice. After dropping the ore of the second slice into the cars below, another fill of waste is run in above the uncovered waste, and the planks are then put back as a cover to separate the waste from the broken ore of the third slice. When, after two or three slices, the waste-floor extends as far as the next raise, the broken ore can henceforth be run into the ore-compartment, and dropping it direct into the drift can cease. The slicing process may then proceed upward, ejecting the broken ore from the chute at one end of the 50-ft. stope, and drawing down the waste for filling from the other end, until the level 200-ft. above is reached. By this system sorting can be done within the stope, leaving the reject there as filling. The back, of course, must be kept well arched and carefully scaled down after each blast before starting to drill.

The earlier custom of drilling either by piston-drill or by hand is now obsolete. The old 265-lb., or even heavier, piston-drill has been replaced by the 165-lb. water-Leyner for driving horizontally or sinking. For cutting out square-set stopes with piston-drills, breast-stopping was most convenient; but now that Rand-stoppers with solid bits are used, back-stopping must be employed. For breaking dry holes the cheaper ammonia-powder has been found to be as good as the nitro-glycerine type, and at the Leonard mine about half of each kind is consumed, the average service being 1.8 tons of broken rock per pound of explosive. For a daily output of 1400 to 1500 tons of ore and 300 tons of waste two shifts of one foreman, two assistant-formen, 26 shift-hoses, and 568 miners and shovelers are employed, with a complement of 45 mechanical and other surface-men, or a total of about 700 men in the 24 hours. This gives an average output of over two tons per man.

In 1900 mules were used underground by the Boston & Montana company, and compressed-air locomotives by the Anaconda. Since the use of the hydro-electric current, the electric motor has become the favorite tractor; not having to deal with explosive gases as in coal mines it is possible to use a 440-volt pressure. When self-dumping skips were first introduced in 1898, they were filled by dumping the cars directly into them at each

level. Now bins are excavated in the floor of each shaft-station, and the 4½-ton skips are filled with one run of the bin instead of with three dumps of the 1500-lb. cars.

When hydro-electric power was introduced a decade ago, it gradually replaced steam as a prime mover in the mines. However, each of the Anaconda's deep shafts was then equipped with steam-hoists, and to discard a dozen serviceable engines that had cost nearly \$50,000 apiece meant a huge loss. The dilemma was avoided by continuing to use the hoists and moving them by air, compressed electrically, instead of by steam. This required only a special pipe-system to feed air to each hoist from a central compressor-plant, and the replacement of the steam-cylinders at the hoists by others that would act as air-compressors to force air back into the system whenever the load was negative. Each hoist is further equipped with a pre-heater for raising the air to 330° F. For all machines save the great hoists, such as drills, portable pumps, and timber-hoists, air is supplied from an individual electric-compressor at each mine. The ownership of numerous adjacent mines by the Anaconda company will permit a common system of levels to be established in all the new lower workings of a group. This will mean easier ventilation; also cheaper transport and drainage. Soon the water from all the mines of the Boston & Montana group will flow to the Leonard and be handled at its 1400 and 2800-ft. levels. At the higher level there are now installed five vertical electric pumps, each with five single-acting plungers and a capacity of 600 gal. per min. against a 1400-ft. head. The lead-lined wrought-iron water-pipes, formerly used in the Anaconda shaft to resist the acid water, are superseded in the later installations by the same pipes lined with creosoted wood. The pump-pistons and adjacent parts are still made of bronze, but a successful experiment was made last year in substituting porcelain for bronze in acid-water pumps.

In 1900 Butte was still in the throes of the consolidation of companies and of the famous lawsuits between Heinze and the Amalgamated company. The latter had been born in 1899 and within 18 months it had absorbed the Anaconda, the Washoe, the Boston & Montana, the Butte & Boston, the Colorado, and the Parrot companies. The lawsuits had been begun against Heinze in 1898 for alleged ore-stealing by the Boston & Montana company, and were a part of the 'assets' inherited by the Amalgamated when it bought out the latter company. Heinze had retaliated by 'carrying the war into Africa' and locating every fraction of unclaimed ground he could find within the central copper zone. He then brought suit against the Amalgamated for the ore removed from the veins, of which his new fractions were the 'apex'. Such are the vagaries of the famous apex law that Heinze's lawsuits, with their rich pickings for lawyers and experts, might have continued to this day had he not grown tired of the fight and sold his copper holdings to his opponent for a big sum. He then went to New York to beard the Standard Oil in its den. This last adventure was more rash than wise, and Heinze's brief plunge into Wall Street nearly wrecked him financially

GRANITE MOUNTAIN SHAFT, WHERE 171 MINERS PERISHED RECENTLY

MAIN STREET, BUTTE, LOOKING NORTH

during the panic of 1907, seven years before his death.

With the absorption, a few years later, of the Original, the Colusa Parrot, and the smaller copper mines of W. A. Clark, the Amalgamated had achieved the ownership of practically all the copper companies that were independent in 1898. Nevertheless the district is still far from being consolidated in the hands of a trust, since many new companies hold ground in the newly developed extensions of the old copper zone. Among these are the Davis-Daly, the East Butte, the North Butte, the Butte Ballaklava, the Tuolumne, the Butte & London, the Butte Duluth, and the Butte & Bacorn, without mentioning such zinc giants as the Elm Orlu and the Butte & Superior. The absorption by the Amalgamated, now the Anaconda, of so many Butte mines has not produced the dire results for labor that were freely predicted as certain to follow the entrance of Standard Oil capital. In 1900 the miners worked 10 hours by day and 9 by night, while smelter-men worked 11 hr. by day and 13 hr. by night. The State 8-hour law was secured by the unions as a by-product of their support of the Heinze-Clark combination against Marcus Daly in the election of 1900. This law is now well observed, and in addition much of the former unnecessary Sunday work has been abolished. A liberal State workmen's compensation law was recently introduced, and has proved a great stimulus to the safety-first movement in Butte. For rescue-work the Anaconda company alone has two stations and 60 Draeger helmets, while the U. S. Bureau of Mines has given valuable instruction in first-aid to resident miners.

It is curious to see Butte an open shop where once was the impregnable stronghold of unionism. There were two reasons for the prolonged prosperity of the Butte Miners' Union. The first was the favor of Marcus Daly, who used to say, "We may pay better here than anywhere else, but then we can afford to, and the bonus will keep them from getting jealous of us mine-owners who got here first and located the bonanza claims." The second was because this union was free from such vicious union practices as lead to restricted membership and output, and never tried to dictate who should be hired or who discharged. Provided all new mine-workers were required by the big companies to pay their union dues of \$1 per month, and the union wages and hours were observed, the union kept the peace between man and master; but like all political democracies, the labor democracies called unions are apt to fall into the hands of a clique. This happened to the Western Federation of Miners, with which the Butte union was always affiliated. The Western Federation clique, justly or unjustly, incurred the enmity of a large number of Butte miners, and the ill feeling culminated on Labor Day in 1913, when the two factions came to blows, and during the battle the local union-hall was blown up by dynamite. Later the State militia had to be called to suppress the disorder, which had undoubtedly been augmented by members of the I. W. W., the American branch of syndicalism or revolutionary anarchy. Since that date the mine-owners have refused to make labor-contracts

with either faction, and the miners have suffered nothing from the change in wages or hours. In fact, the sliding scale of payment, which grants a minimum daily wage to everyone underground\* of \$3.50 and advances it 25c. for every 3c. advance in copper above 15c. per lb., has resulted in equalizing the income of the operatives with the advancing prices of commodities.

The cloud of expensive lawsuits that hung over Butte for a decade proved to have a silver lining. The studies made of the old workings, and the new pits and trenches driven for the elucidation of theories advanced by the mining 'experts', revealed so much of practical value in the finding of orebodies that the geological departments of the companies, founded originally for litigation only, have since continued in action as an indispensable part of their operations. Before 1900 the college graduate was viewed with disfavor in Butte; in fact, to get a job with many managers the less said about one's technical education the better. The practical Cousin Jack, or the 'Paddy-practical,' provided he came from Daly's home county, had his pick of jobs in the mines, mills, and smelters. The Anaconda was the happy haven for the Green Islanders, while the Parrot and the others with Cornish foremen favored men from Cymric England; but today all this is changed, and the technician receives the recognition to which his education entitles him. The Anaconda Consolidated Co. now employs as many in its strictly technical department as did all of the parent companies; while in its geologic bureau, it has over 18 engineers. Moreover it is the policy of this company to introduce into all executive positions, such as superintendent, foreman, or shift-boss, as many technicians as are found suitable. The Butte copper zone is sprinkled so thickly with big rich orebodies that almost every graduate from the end of a shovel could give satisfaction as a boss in the old days merely by getting out plenty of ore, but now 'book-larnin' is having its innings and the 'scientific dudes' are recovering from some of the 'exhausted' upper levels almost as much ore as was ever taken from them in their virgin days. The vast old tailing-piles and slag-dumps, the output of muscular milling and smelting, are also being largely re-treated and they often show a considerably larger metallic content than the old assay-reports indicate. It seems to be proving true that "Assays don't lie, but liars will sample." Besides the above recovery of unmined ore in the upper levels, it has been the custom since 1900 to extract, during all periods of high-priced copper, the filling of low-grade ore in the old stopes. Those dating from the 'eighties may run as high as 10% copper, and those from the 'nineties up to 5%. An old ore-fill is replaced by fresh waste, which is dumped from the cars on the level above, taking waste from cross-cuts in barren rock, and also from old dumps on the surface. Even though it is the custom to fill abandoned drifts as well as stopes with waste, the whole formation around Anaconda hill seems to be moving, and survey-plugs placed in the 'nineties are often found many feet away from their correct position in space.

# Sources of Sulphur in Oils

By G. SHERBURNE ROGERS

\*There are several possible sources of sulphur, though in the Californian fields sulphide waters are probably the most important. The surface and shallow ground-waters in the Californian fields carry large amounts of sodium, calcium, and magnesium sulphate, and outside of the oil-fields the deeper waters are also strongly sulphatic in character. The waters in and near the oil-measures, however, are almost or quite sulphate-free, and are usually solutions of carbonates and chlorides. Between the sulphate surface-waters and the sulphate-free waters associated with the oil, every gradation may be found; and near the horizon at which sulphate begins to decrease and carbonate to increase the waters usually contain hydrogen sulphide. As sulphate is abundant in the shallower waters everywhere along the Californian coast ranges, whereas sulphide is found only in the oilfields and near the oil and gas, it is reasonable to suppose that the sulphide has been formed through the reduction of sulphate by the hydrocarbons. The reaction supposed to be involved is usually written:

Although the field evidence in favor of some such reaction is strong it must be admitted that it has apparently never been experimentally proved. In any event the reaction as written can be considered only as a condensed representation of the type of change that takes place, the intermediate stages in the decomposition of the hydrocarbons on the one hand and of the sulphate on the other being as yet unknown.

In some regions gypsum may be disseminated through the strata near the oil-measures and if taken into solution and carried to the oil may be reduced to sulphide. This is, of course, essentially the same as the reduction of sulphate surface-waters. Gypsum in the anhydrous condition, however, is a very stable compound, and even with an active reducing agent, such as carbon monoxide, a temperature of about 700° C. is required for its reduction. Whether the reduction of sulphate by hydrocarbons takes place or not, it is certain that many of the oilfield waters carry hydrogen sulphide or alkaline sulphide in amounts ranging up to more than 300 parts per million. The tendency of alkaline sulphide to become free  $\text{H}_2\text{S}$ , and the tendency of this gas to oxidize to sulphur, are well known. In this connection the following personal communication from Clifford Richardson is of interest: "Some years ago I collected in a sealed tube 200 or 300 cc. of a natural gas in Trinidad which contained hydrogen sulphide. This was allowed to stand for

about ten years without observation, but at the end of that time it was found that the sulphur of the  $\text{H}_2\text{S}$  was deposited on the walls of the tube in colorless crystals." The oxidation of hydrogen sulphide proceeds even under very feebly oxidizing conditions, as on the floor of the ocean, and it doubtless takes place even in deeply buried strata. In the light of other corroborative evidence, it seems probable that considerable amounts of hydrogen sulphide are oxidized to sulphur, which is precipitated. As the strata directly above the oil-measures have not been tested for sulphur, this supposition cannot be definitely proved, but it is significant that small deposits of disseminated sulphur are not uncommon along the western edges of the Coalinga and Midway-Sunset fields. Moreover, a commercial deposit of sulphur has been found near the southern end of the Sunset field, in the same formation that contains the oil-measures in the field nearby. An interesting feature of this sulphur, to which my attention was first directed by E. A. Starke of the Standard Oil Co., is its intimate mixture with material containing hydrocarbon, which seems to constitute 20% or more of the amorphous substance.

It may be added that the waters associated with the oil in many regions are known to be free from sulphate. In many fields there are strong chloride waters which doubtless represent the sea-water entrapped in the sediments when they were laid down, and which therefore never contained a large concentration of sulphate; but in some fields the low chloride and the high carbonate indicate that the waters are in part altered meteoric waters from which considerable quantities of sulphate have been removed. In some Tertiary and Cretaceous fields in which the normal surface-waters are strongly sulphatic in character the reduction of the sulphate by the stages outlined above may afford abundant supplies of sulphur to react with the oil. Hence, as meteoric waters carry oxygen and also salts that eventually yield sulphur, it is probable that in many regions waters are the chief agents in the alteration of the oil. The apparent increase in the gravity of oil that has been associated with certain types of water is recognized by many practical oil men.

As pyrite is said to react with and to yield sulphur to petroleum it is probable that in some localities the action of both pyrite and its less stable isomer, marcasite, have been important. These minerals have been found in many wells in the Californian fields. They probably formed in part during the deposition of the sediments, through the reducing action of organic matter on iron-sulphate solutions; but they may also have originated later through the direct action of hydrogen sulphide on

\*Abstract: Trans. A. I. M. E., St. Louis meeting, 1917.

chalybeate waters. J. J. Hern, a Californian oil man of wide experience, told me that in wells in which large quantities of iron sulphide are found the oil below is likely to be abnormally warm. If this observation is well founded, it may be significant as indicating chemical reaction between the sulphide and the oil. In some regions sulphur is doubtless derived from still other sources. Hydrogen sulphide and sulphur di-oxide are common components of volcanic emanations, and the former is found in many thermal springs supposed to represent the last stages of igneous activity. Much of the Mexican oil, which is heavy, asphaltic, and high in sulphur, is found near igneous intrusions and may well have been affected by the sulphurous gases that doubtless accompanied them. The oil in the salt-domes of the Gulf Coast is somewhat similar in character and has evidently been altered by sulphur, but the origin of the sulphur in this case is related to that of the salt-domes themselves, and has never been satisfactorily explained. Again, it has long been known that some varieties of bacteria have the property of generating hydrogen sulphide through the reduction of sulphate solutions. Some of these bacteria are anaerobic, being able to exist in the absence of air, and their action has been repeatedly observed in ocean water, but whether they can exist and function in deeply buried strata is open to question. Finally, there are oils, like those of the Appalachian fields, that have apparently never been subjected to the action of sulphur; and others, like the Trenton limestone oil of Ohio, that are generally supposed to owe their sulphur to the character of the organic remains from which they were formed. If the organic origin of petroleum is accepted the old idea that the contained sulphur indicates derivation from animal remains is not necessarily valid. It is generally recognized, however, that the character of the original organic material has a bearing on the composition of the oil derived from it.

## Mine Found by Thieves

How a Brazilian physician owes a prospective fortune to the cupidity of negro thieves is revealed in a little story which comes from Rio Janeiro. According to this tale, Dr. Marques da Silva rented a house in a suburb of Rio Janeiro to a family of negroes. After remaining in the house long enough to run up a good-sized unpaid rent bill, the negroes suddenly decamped, taking with them all the electric wiring and plumbing fixtures in the house. They even tore up a lead pipe leading underground to a water-main.

Dr. da Silva went through the looted house, sadly noting his losses and the damage done to the premises, and sat down on the veranda to think over the iniquity of his missing tenants. Suddenly he noticed a peculiar metallic gleam in the trench where the pipe had been torn out. The gleam was caused by mercury oozing from the clay. The mercury mine probably will make the doctor a millionaire.—*Daily Metal Reporter*.

## A Blast-Furnace Record

Ten tons per square foot of hearth-area is the record made by a 14-ft. blast-furnace at the smelting plant of the Consolidated Arizona Smelting Co.'s smelter at Humboldt, Arizona. It is a rectangular water-jacketed furnace, 14 ft. long and 52 in. wide at the tuyeres. It taps from the side through a water-cooled copper breast-jacket with a water-jacketed spout, and a water-cooled copper lip into a pear-shaped settler 27 ft. long and 13 ft. wide and 55 in. deep. It has practically no crucible, as it is bricked up to within 3 in. of the tuyeres on each end and the bottom slopes toward the middle so that it is just below the connection hole at the centre. The furnace is fed mechanically with six charge-cars of the old Anaconda type, having a capacity of 60 cu. ft. each, and dumped by means of an air-lift.

### DETAILS OF FURNACE

Width at tuyeres .....	52 in.
Length of furnace .....	168 in.
Square feet hearth-area .....	60.66
Height of furnace .....	11 ft. 6 in.
Distance from tuyeres to top .....	8 ft. 6 in.
Distance from tuyeres to sole plate .....	3 ft. 6 in.
Diameter of tuyeres .....	4 in.
Centre to centre between tuyeres .....	15 in.
Number of tuyeres .....	22
Tuyere-area .....	276.46 sq. in.
Tuyere-area per square foot of hearth-area .....	4.56 in.
Cubic feet of air per minute .....	20,000
Air-pressure .....	26 to 30 oz.
Tons smelted per 24 hr. ....	609
Tons per square foot of hearth-area per 24 hr. ....	10.04
Per cent coke .....	9.3%

The charge is put in as follows: two cars of coke holding 800 lb. each are dumped in, and then two ore-cars holding 8000 lb. each are dumped on top of it from the same side of the furnace, and this is repeated on the other side of the furnace for the next charge. The charge consists of ore, converter-slag, and limestone, and has the following composition:

	%
SiO <sub>2</sub> .....	33.5
Fe .....	26.8
CaO .....	8.6
S .....	10.4
Cu .....	3.12

With an 80% sulphur-elimination this gives a 38% matte and a slag assaying:

	%
SiO <sub>2</sub> .....	40
Fe .....	30
CaO .....	10.2
Cu .....	0.25

The smelter superintendent in charge is F. K. Brunton.

PETROLEUM development in Louisiana is approaching near to the city of New Orleans. Wells are being drilled within 40 miles of that city by the Concordia Gas & Oil Co. The oil and gas zone has now been shown to extend from Natchez to a point south of New Orleans.

# Survey of Inclines Without Auxiliaries

By A. J. SALE

In an out of the way district, an engineer may sometimes be called upon to make a survey down a steep incline when he has no auxiliary telescope available. If this should happen, he will find that the following method readily solves the difficulty. Necessity having forced me to evolve this procedure, I became so attached to it that I have since ceased to use auxiliaries where accuracy is an important factor. At best, either a top or side telescope has many disadvantages. They are hard to keep in adjustment, they greatly detract from the stability of the 'set up,' and introduce awkward corrections into the calculations. The essence of the problem is to generate a vertical plane down the incline; the remainder is merely detail. For this type of work, it stands to reason that the instrument must be in perfect adjustment, but, in addition to the usual transit adjustments, including both the one for leveling and the one of the vertical vernier, there is another condition that must be investigated. By the 'peg adjustment,' or otherwise, one can apparently make the bubble-tube of the telescope parallel to the line-of-sight; but, in reality, it only causes them to lie in parallel planes, and, in an inclined position of the plate, they would show false conditions. This special adjustment is made in the following manner: Select two parallel walls, about 100 ft. apart, and mark an approximate centre line between them. Have all three of the legs of the transit at equal length, and place them as indicated in Fig. 1. Loosen the leveling screws under the plate and turn the head of the machine until a pair of opposite screws lies in a line approximately parallel to the marked centre line. This forces the other pair into a position approximately perpendicular to this line. Tighten all of the leveling screws, and level the plate. With the vertical motion, bring the bubble of the telescope into a central position, causing the vertical vernier to read 0. Set the plate-vernier to read 0, and, with the lower motion, turn until the telescope points forward along the marked centre line. This causes one of the plate bubble-tubes to be approximately perpendicular to the centre line. With the upper motion, turn to 90°. (As the upper motion is used throughout the remainder of this adjustment, I will not repeat the mention of it.) Mark a point where the line-of-sight intersects the wall. Then, leaving the vertical motion fixed, mark another point at the same level, but at about 2 ft. in advance of the last. With a straight-edge, draw a line connecting these points. In like manner, after turning to 270°, mark another line on the opposite wall. By this method there will have been drawn two horizontal lines at the same elevation. Now, by shortening the forward leg, cause the plate to be-

come inclined to any desired angle, which may be called  $\theta$ . It is best to make this inclination to some special angle such as 15° or 30°, depending upon the steepness of the incline to be surveyed. For very steep inclines, 30° or more may be necessary.

It is a simple matter to set this angle of inclination. Suppose 20° is desired: Set the vertical vernier to read +20°; lower the forward leg of the instrument until the telescope-bubble approaches a level position, then bring it exactly level by means of the leveling-screws which lie parallel to the centre line. After having set  $\theta$ , level the bubble-tube which lies perpendicular to the centre line. (This operation is not absolutely necessary, but saves time by bringing the instrument into approximate position.) Set the vertical vernier to read 0, and turn the plate to 90°. (As the instrument has been brought into perfect adjustment, the line of sight will be parallel to the plate when the vertical vernier reads 0.) Mark the point where the line of sight cuts the wall. (Since the general position of the machine has been lowered, this point will usually be a few inches below the horizontal line already marked.) Now, leaving the vertical motion fixed, turn to 270° and mark the point where the line of sight cuts that wall. Measure the distance from each of these points to its corresponding horizontal line. From each point mark off one-half of the difference between these measurements in the direction in which it occurs.

As an example: Suppose, at the 90° position the point is 3 in. below its line, while at the 270° position it is 3½ in. below. Then, at the 90° position, mark a new point ½ in. below the original; while at the 270° position mark a new point ½ in. above the original. Through each of these new points draw a short horizontal line. (These lines may not be necessary; but, as there is a tendency toward a horizontal movement in the next change of the telescope, they will probably save time.) Leaving the vertical motion fixed, and by means of the pair of leveling-screws which lie perpendicular to the centre line, raise or lower the line of sight until it cuts the new short horizontal line just marked. Then turn back to the 90° position, where the line of sight should exactly cut the new line which has just been marked for that position. If there is a slight discrepancy, correct half at both positions as has been described. Now turn back to the position and re-set  $\theta$ , if it shows any change. If any correction is made in  $\theta$ , it will be necessary to turn back to both the 90° and 270° positions and correct any small errors that may have occurred, after which it will not be necessary to re-set  $\theta$ .

By the above operations a horizontal line is fixed into

chalybeate waters. J. J. Hern, a Californian oil man of wide experience, told me that in wells in which large quantities of iron sulphide are found the oil below is likely to be abnormally warm. If this observation is well founded, it may be significant as indicating chemical reaction between the sulphide and the oil. In some regions sulphur is doubtless derived from still other sources. Hydrogen sulphide and sulphur di-oxide are common components of volcanic emanations, and the former is found in many thermal springs supposed to represent the last stages of igneous activity. Much of the Mexican oil, which is heavy, asphaltic, and high in sulphur, is found near igneous intrusions and may well have been affected by the sulphurous gases that doubtless accompanied them. The oil in the salt-domes of the Gulf Coast is somewhat similar in character and has evidently been altered by sulphur, but the origin of the sulphur in this case is related to that of the salt-domes themselves, and has never been satisfactorily explained. Again, it has long been known that some varieties of bacteria have the property of generating hydrogen sulphide through the reduction of sulphate solutions. Some of these bacteria are anaerobic, being able to exist in the absence of air, and their action has been repeatedly observed in ocean water, but whether they can exist and function in deeply buried strata is open to question. Finally, there are oils, like those of the Appalachian fields, that have apparently never been subjected to the action of sulphur; and others, like the Trenton limestone oil of Ohio, that are generally supposed to owe their sulphur to the character of the organic remains from which they were formed. If the organic origin of petroleum is accepted the old idea that the contained sulphur indicates derivation from animal remains is not necessarily valid. It is generally recognized, however, that the character of the original organic material has a bearing on the composition of the oil derived from it.

# Survey of Inclines Without Auxiliaries

By A. J. SALE

In an out of the way district, an engineer may sometimes be called upon to make a survey down a steep incline when he has no auxiliary telescope available. If this should happen, he will find that the following method readily solves the difficulty. Necessity having forced me to evolve this procedure, I became so attached to it that I have since ceased to use auxiliaries where accuracy is an important factor. At best, either a top or side telescope has many disadvantages. They are hard to keep in adjustment, they greatly detract from the stability of the 'set up,' and introduce awkward corrections into the calculations. The essence of the problem is to generate a vertical plane down the incline; the remainder is merely detail. For this type of work, it stands to reason that the instrument must be in perfect adjustment, but, in addition to the usual transit adjustments, including both the one for leveling and the one of the vertical vernier, there is another condition that must be investigated. By the 'peg adjustment,' or otherwise, one can apparently make the bubble-tube of the telescope parallel to the line-of-sight; but, in reality, it only causes them to lie in parallel planes, and, in an inclined position of the plate, they would show false conditions. This special adjustment is made in the following manner: Select two parallel walls, about 100 ft. apart, and mark an approximate centre line between them. Have all three of the legs of the transit at equal length, and place them as indicated in Fig. 1. Loosen the leveling screws under the plate and turn the head of the machine until a pair of opposite screws lies in a line approximately parallel to the marked centre line. This forces the other pair into a position approximately perpendicular to this line. Tighten all of the leveling screws, and level the plate. With the vertical motion, bring the bubble of the telescope into a central position, causing the vertical vernier to read 0. Set the plate-vernier to read 0, and, with the lower motion, turn until the telescope points forward along the marked centre line. This causes one of the plate bubble-tubes to be approximately perpendicular to the centre line. With the upper motion, turn to 90°. (As the upper motion is used throughout the remainder of this adjustment, I will not repeat the mention of it.) Mark a point where the line-of-sight intersects the wall. Then, leaving the vertical motion fixed, mark another point at the same level, but at about 2 ft. in advance of the last. With a straight-edge, draw a line connecting these points. In like manner, after turning to 270°, mark another line on the opposite wall. By this method there will have been drawn two horizontal lines at the same elevation. Now, by shortening the forward leg, cause the plate to be-

come inclined to any desired angle, which may be called  $\theta$ . It is best to make this inclination to some special angle such as 15° or 30°, depending upon the steepness of the incline to be surveyed. For very steep inclines, 30° or more may be necessary.

It is a simple matter to set this angle of inclination. Suppose 20° is desired: Set the vertical vernier to read +20°; lower the forward leg of the instrument until the telescope-bubble approaches a level position, then bring it exactly level by means of the leveling-screws which lie parallel to the centre line. After having set  $\theta$ , level the bubble-tube which lies perpendicular to the centre line. (This operation is not absolutely necessary, but saves time by bringing the instrument into approximate position.) Set the vertical vernier to read 0, and turn the plate to 90°. (As the instrument has been brought into perfect adjustment, the line of sight will be parallel to the plate when the vertical vernier reads 0.) Mark the point where the line of sight cuts the wall. (Since the general position of the machine has been lowered, this point will usually be a few inches below the horizontal line already marked.) Now, leaving the vertical motion fixed, turn to 270° and mark the point where the line of sight cuts that wall. Measure the distance from each of these points to its corresponding horizontal line. From each point mark off one-half of the difference between these measurements in the direction in which it occurs.

As an example: Suppose, at the 90° position the point is 3 in. below its line, while at the 270° position it is 3½ in. below. Then, at the 90° position, mark a new point ¼ in. below the original; while at the 270° position mark a new point ¼ in. above the original. Through each of these new points draw a short horizontal line. (These lines may not be necessary; but, as there is a tendency toward a horizontal movement in the next change of the telescope, they will probably save time.) Leaving the vertical motion fixed, and by means of the pair of leveling-screws which lie perpendicular to the centre line, raise or lower the line of sight until it cuts the new short horizontal line just marked. Then turn back to the 90° position, where the line of sight should exactly cut the new line which has just been marked for that position. If there is a slight discrepancy, correct half at both positions as has been described. Now turn back to the position and re-set  $\theta$ , if it shows any change. If any correction is made in  $\theta$ , it will be necessary to turn back to both the 90° and 270° positions and correct any small errors that may have occurred, after which it will not be necessary to re-set  $\theta$ .

By the above operations a horizontal line is fixed into

which the line of sight falls at both the  $90^\circ$  and  $270^\circ$  positions. Notice the position of the telescope-bubble at each of them. (The inclination of the plate causes the bubble to be near the upper side of its tube, but that does not prevent a satisfactory determination of its position). If the bubble-tube happen to be exactly parallel to the line of sight, the bubble will be in the central point at both the  $90^\circ$  and  $270^\circ$  positions. But if it is warped from a parallel by a small angle, which may be called  $\mu$ , the bubble will be off centre at one position, and an equal amount in the opposite direction at the other. If one did not account for the effect of the angle  $\mu$ , and assumed that the line of sight was horizontal when the bubble was in a central point at either  $90^\circ$  or  $270^\circ$ , the result would be that the line-of-sight would make a small angle with the horizontal at the  $90^\circ$  position, and an equal angle with opposite sign at  $270^\circ$ . In later operations, either turn the telescope from  $270^\circ$  to  $360^\circ$ , or from  $90^\circ$  to  $0$ , which will bring the horizontal axis of the telescope to either the  $270^\circ$  or  $90^\circ$  position of the line-of-sight, and the final effect is the same as if the plate were in normal position, and the horizontal axis of the telescope inclined by a small angle, which call  $\nu$ ; this angle being the vertical projection of the angle  $\mu$ .

Now it might be possible to shift the bubble-tube so that it did lie parallel to the line of sight, and make the regular bubble-adjustment afterward; but this amount of work is entirely unnecessary. If it so happen that the bubble-tube is exactly parallel to the line of sight, trouble of inclining the plate to a fixed angle will be saved, but that is the only advantage. The vital feature of the proposition is to mark the exact positions of the bubble which force a horizontal condition of the line of sight at both the  $90^\circ$  and  $270^\circ$  positions. This marking can be done by taking narrow strips of paper and pasting them on the bubble-tube at the ends of the bubble. Considerable error is allowable in setting  $\theta$ , without seriously affecting the carrying of true bearings.

By descriptive geometry, it can be demonstrated that  $tg \nu = tg \mu \sin \theta$ . (In Fig. 2, I indicate how this demonstration is made.) To study the relative errors, apply a simple principle of calculus and differentiate relative to  $\nu$  and  $\theta$ . Differentiating:

$$tg \nu = tg \mu \sin \theta$$

$$\frac{1}{\cos^2 \nu} \cdot d, \nu = tg \mu \cdot \cos \theta \cdot d, \theta$$

$$\text{But } \frac{1}{\cos^2 \nu} = 1 + tg^2 \nu = 1 + tg^2 \mu \cdot \sin^2 \theta$$

Therefore

$$d, \nu = \frac{tg \mu \cdot \cos \theta}{1 + tg^2 \mu \cdot \sin^2 \theta} \cdot d, \theta$$

Now, since  $\mu$  is a very small angle,  $tg^2 \mu \cdot \sin^2 \theta$  is negligible as compared with unity.

Therefore  $d, \nu = tg \mu \cdot \cos \theta \cdot d, \theta$ .

Now suppose that it is required to lock down a steep angle, which call  $\phi$ , with the result that the inclination of the horizontal axis of the telescope (angle  $\nu$ ), causes an error in the bearing, which call  $\psi$ .

It can be demonstrated that

$$tg \psi = tg \phi \cdot \sin \nu$$

(This demonstration is indicated in Fig. 3.)

Differentiating relative to  $\psi$  and  $\nu$ , it appears that

$$\frac{1}{\cos^2 \psi} \cdot d, \psi = tg \phi \cdot \cos \nu \cdot d, \nu$$

$$\text{But } \frac{1}{\cos^2 \psi} = 1 + tg^2 \psi = 1 + tg^2 \phi \cdot \sin^2 \nu$$

$$\text{Therefore } d, \psi = \frac{tg \phi \cdot \cos \nu}{1 + tg^2 \phi \cdot \sin^2 \nu} \cdot d, \nu$$

But, since  $\nu$  is even less than  $\mu$ ,  $tg^2 \phi \cdot \sin^2 \nu$  is negligible as compared to unity; and, for practical results,  $\cos \nu$  can be taken as unity, making  $d, \psi = tg \phi \cdot d, \nu$ .

Substituting for  $d, \nu$  its previously derived value, there results

$$d, \psi = tg \phi \cdot d, \nu = tg \phi \cdot tg \mu \cdot \cos \theta \cdot d, \theta$$

To apply this formula practically, assume:

$$\theta = 75^\circ$$

$\mu = 30'$ . (It is extremely improbable that  $\mu$  will ever be as much as  $10'$ .)

$$\theta = 30^\circ$$

Also assume that, in attempting to set  $\theta$  at  $30^\circ$ , an error of  $30'$  is made.

Applying the above values in the formula:

$$d, \psi = tg 75^\circ \cdot tg 30' \cdot \cos 30^\circ \cdot d, \theta = 0.0282 \cdot d, \theta$$

And, since  $d, \theta$  was taken at  $30'$ ,  $d, \psi = 0.846' = 0^\circ, 00', 50''$ .

In other words, an error of half a degree in setting the plate only amounts to 50 seconds in future bearings.

The method of operation of the adjusted machine is as follows: Place the transit in a firm position at the top or the incline, with two of its legs close to the collar, and the third in a symmetrical position. Loosen the leveling screws and turn the head of the machine until a pair of opposite screws is approximately in the line of the incline. Tighten the leveling screws, and incline the plate to the required angle  $\theta$  as previously described. Set the upper motion to read 0, and, with the lower motion, turn until the telescope points along the general direction of the incline. This will bring one of the plate-bubbles in line with and perpendicular to this line. Level this bubble, using the pair of leveling screws which lie perpendicular to the line of sight. (The position of the machine is shown in Fig. 4.)

Now, at some convenient point close to the incline in the underground workings, place an over-head plug containing a perforated horse-shoe nail or other suitable eye-point (X, Fig. 4). Drop a plumb-line to the floor and mark the point X' directly under X. Place an illumination behind X'; and, using the lower motion, focus upon the plumb-line at any convenient point. (The vertical cross-hair will probably be at a small angle to the plumb-line.) The plate bubble-tube will probably get out of level; but that is of no importance, as it was only levelled to bring the machine into approximate position. With the upper motion, turn an angle of  $90^\circ$ ; and, by means of the vertical motion, bring the telescope-bubble to the point marked for a horizontal condition of

the line-of-sight at the  $90^\circ$  position. Continuing with the upper motion, turn to  $270^\circ$ . The telescope-bubble will deviate by a considerable amount from the point which has been marked to enforce a horizontal line of sight at the  $270^\circ$  position. Correct half of this amount by means of the vertical motion, and the other half with the pair of leveling screws which lie at right angles to the line-of-sight. Continuing with the upper motion, turn back to 0. The vertical cross-hair should now be very nearly parallel with the plumb-line. Using the lower motion, focus exactly upon the plumb-line. Re-check  $\theta$ , and, if it is in error, re-set it. (This is the last time that it will be necessary to bother with this angle, as it has been demonstrated that a small change in it will not materially affect the accuracy of the work.)

If any change has been made in  $\theta$ , re-focus upon the plumb-line, using the lower motion. Repeat the operations at the  $90^\circ$  and  $270^\circ$  positions. This time the amount of bubble-correction will probably be very small; and, on the final turn to 0, the vertical cross-hair should exactly coincide with the plumb-line; if not, repeat until it does. (After the final leveling, the vertical vernier should read exactly 0 at both the  $90^\circ$  and  $270^\circ$  positions.)

The problem is now practically solved, except for a few working details which will be described later, for there has been developed such a condition that, when the telescope is focused on the plumb-line, and rotated around its horizontal axis, it will generate a vertical plane through the plumb-line. The demonstration of this is as follows: In Fig. 5 the operator is looking along the

line of the incline and parallel to the plate.  $M-N$  represents a horizontal line and  $A-B$  the position of the line-of-sight, after leveling at the  $90^\circ$  position.  $O-P$  represents the axis of the socket which, since the instrument is in perfect adjustment, passes through the line-of-sight, and is also perpendicular to the plane of the plate. Assume a plane passing through the line-of-sight and the axis of the socket and let it intersect the plane of the plate at  $C-D$ . Now,  $\angle OPC = 90^\circ = \angle OPD$ ; because the axis of the socket, being perpendicular to the plane of the plate, must be perpendicular to an intersecting line in that plane. Also assume that  $C-D$  makes an angle ( $\angle OMP$ , Fig. 5) with  $M-N$ . Now the telescope is rotated  $180^\circ$  (that is, from  $90^\circ$  to  $270^\circ$ ) around the axis  $O-P$ . Let  $A'-B'$  represent the rotated position of  $A-B$ . The total deviation is  $\angle AOB'$ , or  $\angle A'O B$ . Half of this is to be corrected by the vertical motion, and half by the leveling screws which lie in a line perpendicular to the line of the incline. Assume that the first correction brings  $A'-B'$  to  $A''-B''$ , in which case  $\angle A'O A'' = \frac{1}{2} \angle A'O B$  or  $\angle A'O B'' = \frac{1}{2} \angle A'O B$ , which means  $\angle A'O B' = 2 \angle A'O B''$ .

Next consider  $\triangle MPO$ :  $\angle MPO = \angle OPC = 90^\circ$ . Therefore  $\angle MOP = 90^\circ - \angle OMP$ . But, since  $A-B$  is rotated around  $O-P$ ,  $\angle A'OP = \angle AOP = \angle MOP = 90^\circ - \angle OMP$ .

Therefore

$$\angle AOA' = \angle AOP + \angle A'OP = 2 \angle AOP = 2(90^\circ - \angle OMP) = 180^\circ - 2 \angle OMP.$$

But,  $A-B$  being a straight line,  $\angle A'OB = 180^\circ -$

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

$$\angle AOA' = 180^\circ - (180^\circ - 2 \angle OMP) = 2 \angle OMP.$$

But  $\angle A'OB = \angle AOB'$ . Therefore  $\angle AOB' = 2 \angle OMP$ .

But  $\angle AOB' = 2 \angle AOB''$ .

Therefore  $\angle AOB'' = \angle OMP$ , or  $A''B''$  is parallel to  $C-D$ .

Now the second correction causes a rotation around the centre of the ball and socket joint below the plate to such an extent that the line-of-sight becomes horizontal.  $O$  goes to  $O'$ ;  $A''B''$  to  $A'B'$ ;  $P$  to  $P'$ ; and  $C-D$  to  $C'D'$ . But, as this second correction does not change the relative position of these lines as regards each other,  $C'D'$  will be parallel to  $A'B'$ , and  $\angle O'P'D' = \angle O'P'C' = \angle OPC = 90^\circ$ . But this rotation caused  $A'B'$  to be a horizontal line, therefore,  $C'D'$  is a horizontal line.

Now consider the plane which would be generated by the rotation of the line-of-sight around the horizontal axis of the telescope in the final (or  $360^\circ$ ), position: Referring to Fig. 6, this plane is shown as  $O'C''P'D''$ . ( $C''$  and  $D''$  being the respective positions of  $C'$  and  $D'$ , after the rotation from the  $270^\circ$  to the  $360^\circ$  position.) The  $\angle O'P'D' = 90^\circ$ , from the previous demonstration. Also  $\angle D'P'D'' = 90^\circ$ , due to the turn from  $270^\circ$  to  $360^\circ$ . Therefore the line  $C'D'$ , being perpendicular to the line  $O'P'$ , also perpendicular to the intersecting line  $P'D''$ , must be perpendicular to the plane  $O'C''P'D'$ . Therefore the plane  $O'C''P'D''$  is perpendicular to the line  $C'D'$ . But the line  $C'D'$  has been demonstrated to be a horizontal line. Therefore the plane of rotation will be a vertical plane.

This has prepared the way for the final details: At some convenient position ( $Y$ , Fig. 4) place a survey-plug in the line-of-sight and drive in a perforated horse-shoe nail. Drop a plumb-line from this point, and drive over the horse-shoe nail until it comes exactly into line. The point  $Y$  should be so selected that when the plumb-line is let down as far as possible the lower end will be visible from the 'set up' under  $X$  by raising the telescope to an angle of about  $45^\circ$ . As this system is only required for inclines whose dip exceeds  $45^\circ$ , it is evident that the plumb-line will reach a considerable way down the shaft before touching the floor. It is best to set at least two of these points to make sure of obtaining a back-sight with as long a base as possible. After setting  $Y$ , rotate the telescope around its horizontal axis, until it looks over the collar of the incline, and place a hub ( $Z$ , Fig. 4) in line and close to the incline. Drive a tack exactly in the line of sight. Also place another hub and tack in the same line but several hundred feet away ( $Z'$ , Fig. 4). Since it has been demonstrated that the line-of-sight rotates in a vertical plane, these hubs can be either forward of back-sights. Having set the hubs, the next operation is to read the exact value of  $\theta$ , after leveling the telescope-bubble at the 0 position. It was previously demonstrated that, without seriously affecting the generating of a vertical plane, it is allowable to take considerable margin in setting  $\theta$  to a fixed angle; but the exact value of  $\theta$  must be used to obtain true

vertical angles. To obtain any true vertical angle, algebraically subtract the value of  $\theta$  from the vertical angle as read. Only angles lying in the generated vertical plane are to be used.

Suppose  $\theta = 30^\circ$ :

Then, for an apparent vertical angle of  $+40^\circ$ , the actual vertical angle will be  $+40 - 30 = +10^\circ$ , while for an apparent vertical angle of  $-40^\circ$  it will be  $-40 - 30 = -70^\circ$ .

If it become necessary to use back-sight positions, involving the use of a reversed telescope, the angle  $\theta$  must be algebraically added. In the above case an apparent back-angle of  $-10^\circ$  will be a true angle of  $-10^\circ + 30^\circ = +20^\circ$ . An apparent back angle of  $-30^\circ$  will be a true angle of  $-30^\circ + 30^\circ = 0^\circ$ , or horizontal, while an apparent back angle of  $-60^\circ$  will be a true angle of  $-60^\circ + 30^\circ = -30^\circ$ .

The remaining operation from this 'set-up' is to tape the distances to the nearest hub ( $Z$ , Fig. 4), and to the point  $X'$  (Fig. 4), and read the apparent vertical angles. Both the horizontal and vertical distances are obtained by this operation.

Suppose:  $\theta = 30^\circ$ ,  $30'$ ; and the tape reading to  $Z$  is 15.15 ft., with an apparent vertical angle of  $+(25^\circ, 20')$ ; then the actual vertical angle is  $+(25^\circ, 20') - (30^\circ, 30') = -(5^\circ, 10')$ , and the horizontal distance between the instrument and the hub is 15.15 ft. times  $\cos(5^\circ, 10')$ ; while the 'H. I.,' relative to the hub, will be  $+ [15.15 \text{ ft. times } \sin(5^\circ, 10')]$ .

Also suppose the tape reading to  $X'$  to be 225.20 ft. with an apparent vertical angle of  $-(38^\circ, 10')$ ; this makes the actual vertical angle  $-(38^\circ, 10') - (30^\circ, 30') = -(68^\circ, 40')$ , and the horizontal distance between the instrument and point  $X$  will be 225.20 ft. times  $\cos(68^\circ, 40')$ ; while the floor of the level (point  $X'$ ) will be 225.20 ft. times  $\sin(68^\circ, 40')$  below the 'H. I.'

The final operation to complete the surface-work is to tie in  $Z$  from some other station; set on  $Z$  and get the bearing of  $Z-Z'$ ; and to obtain the elevation of  $Z$  relative to a known bench mark.

There is now a complete survey down the incline, covering bearings, horizontal distances, and elevations. It only remains to set under  $X$  (that is, over  $X'$ ), back-sight to the plumb-line from  $Y$ , and continue as desired. In making the back-sight from the 'set-up' under  $X$ , it is best to raise the telescope as much as convenient in order to look as far back up the incline as possible. If several points  $Y$  have been set, there is a chance that a much longer back-base can be obtained than was even suspected at the start.

If more than one level is to be tied in, it is best to make the first point ( $Y$ ) at the bottom level, and then place points on the other levels in the manner described for setting  $Y$ . If it is necessary to carry a survey up an incline, it is best to work downward from the top, and tie in the line below afterward. A triangular eyepiece is a convenient help to save kinks in the neck of the operator, but its use is not absolutely necessary.

The method described will rapidly and accurately

solve the problem of carrying a survey down any steep incline of a reasonable depth, but, for a very deep incline, some special considerations are advisable. Suppose the incline to be very steep, and a 1000 ft. or more deep. Under these conditions, as it is not probable that the point  $Y$  can be placed at more than 20 or 30 ft. from point  $X$ , there will be involved all the errors connected with a long sight in setting both the points  $Y$  and  $Y'$ : while one will have to depend upon a very short back-sight under ground. Even under these conditions, if due care be used, the errors will be comparatively small, and this method will prove sufficiently accurate for any ordinary work, but, for work where unusual accuracy is required, I would recommend the following procedure: Set point  $Y$  where it can be easily seen from an ordinary 'set-up' under  $X$ . Also set an additional point, which call  $Y'$ , in line and up near the collar of the incline. Everything else is done as previously described. When prepared to work below, mark a line on the floor, through  $X'$ , and approximately in the general direction of the incline. Have the three legs of the instrument at equal length and set over  $X'$  (that is, under  $X$ ), in such a position that the back leg of the machine, from a position looking up the incline, lies in the line just drawn, while the forward ones are placed symmetrically. The reverse of the position shown in Fig. 1 will produce this condition. Make an accurate 'set-up' over  $X'$  with as little relative change in the legs as possible. Loosen the leveling screws under the plate and turn the head of the instrument until a pair of opposite leveling screws is in an approximate line with the incline. Tighten the leveling screws, level the plate, set the upper-motion to read 0, and, with the lower-motion, turn until the telescope points in a line directly reversed to that up the incline. Set the required angle  $\theta$ , tilt the plate, and do the leveling at the  $90^\circ$  position and the half and half correction at  $270^\circ$ , as previously described. Loosen the vertical motion, set the upper-motion at  $180^\circ$  and, by means of the lower-motion, focus upon a plumb-line dropped from  $Y'$ .

If proper precaution has been taken in regard to symmetry, a plumb-line dropped from  $Y$  will come within the range of vision by changing the focus; and a lateral shifting of the plate should bring the line-of-sight into the line  $Y'-Y$ , without altering the position of the legs. Should the amount of required shifting exceed the limits of the plate, move each leg by the same amount in the same direction so as to keep the general position uniform. After the line-of-sight has been brought into the line  $Y'-Y$ , turn back to 0; re-set  $\theta$ , and repeat the operations. It is now probable that, when the line-of-sight has been focused upon  $Y'$ ,  $Y$  will only deviate by a very small amount from being in line, and, after making the required shift of the plate, and repeating the complete operation, the line-of-sight should be exactly in the line  $Y'-Y$ ; if not, repeat until it does. If proper preliminary judgment as to symmetry has been used this whole amount of maneuvering should not take more than twice the time usually required to set in line

with two plumb-lines, and its accuracy can be more fully depended upon.

After these operations have been completed, if the line-of-sight is brought into position and rotated around the horizontal axis of the telescope, it will generate a vertical plane up the incline through the points  $Y'$  and  $Y$ . The only remaining operation is to fix this plane by setting two points, one close to the machine, and the other as far away as convenient. In continuing the underground work it is advisable to use only this new line for meridian, as the points  $X$  and  $X'$  may vary by a small amount from it, but, as this variation will be very small, it will be safe enough to carry distances and elevations from the old points.

While it has taken considerable space to describe this modus operandi and to make clear its mathematical demonstration, a practical trial by any engineer should convince him that in its field application the method is rapid, the resultant office calculations simple, and the final result the attainment of a degree of accuracy which cannot be reached by any auxiliary attachments.

BARYTES, or barium sulphate, is used chiefly in making mixed paints, in which white, ground, and water-floated barite is employed as a pigment. Ground barite is also used in the rubber industry and to some extent by the makers of heavy glazed paper and ink. Lithopone, a chemically prepared white pigment consisting of about 70% barium sulphate and 30% zinc sulphate, is one of the chief constituents of the 'flat' wall-paints so extensively used in office-buildings and hospitals, replacing the less desirable paper and calcimine wall-finishes. Its larger use is in the manufacture of linoleum, and as an adulterant in making rubber tires. Since the beginning of the War a barium chemical industry has been established in the United States to supply barium carbonate, nitrate, chloride, chlorate, hydrate, and dioxide, formerly imported largely from Germany. In 1915 this consumed 10% of the domestic barite, but the consumption in 1916 was somewhat larger. The barium chemicals have a wide variety of applications, perhaps the most important being the use of barium dioxide in the preparation of hydrogen peroxide, that of barium chloride as a water softener; other various salts are used in the manufacture of optical glass. Barytes is mined principally in Missouri, northwestern Georgia, east-central Tennessee, central and western Kentucky, north-eastern Alabama, south-western North Carolina, north-western South Carolina, and south-western Virginia. The price now ranges from \$28 to \$32 per ton for prime white or floated material.

ARGENTINA is developing oil-fields in Patagonia and in other parts of the republic. A recent report by the Argentine Bureau of Mines affirms that the petroleum deposits of Rivadavia on the Patagonian coast promise to rank among the most important of the world. The oil is found at a depth of about 1600 ft. below sea-level. By distillation it yields 5% benzene, 16.27% of illuminating oil, and 67% heavy oil.

# Chromite

By J. S. DILLER

\*The importance of chromite in the manufacture of armor plate, armor-piercing projectiles, stellite for high-speed tools, and automobile and other special steels can scarcely be overestimated. The chief sources of supply for the United States during the last few years have been Rhodesia, New Caledonia, Turkey, and Greece. Embargoes were placed on the shipment of chrome ore from some of the principal sources, and it was feared that the supply for the United States would be cut off, but after the producers received a guaranty that the ore would not be re-shipped to enemy-belligerents the imports, as shown in the following table, greatly increased, especially those from Rhodesia, New Caledonia, and Canada, though those from Greece have declined slightly and those from Turkey have entirely ceased.

CHROMIC IRON IMPORTED INTO THE UNITED STATES, 1913-1916,  
IN LONG TONS

	1913	1916
Cuba .....		34
Canada .....		10,930
England .....		5
Greece .....		7,900
Japan .....	322	.....
French Oceania .....	6,620	30,950
Australia .....		2,986
British South Africa.....		23,000
Portuguese Africa .....	29,000	38,850
Turkey in Asia .....	13,830	.....
	49,772	114,655

Chromic iron produced and sold in the United States, 1913 and 1916, was respectively 255 and 40,000 long tons. The greatly increased trade, especially in steel, and the consequently larger demand for chromite, have stimulated the search for it in the United States, as shown by the large increase in production. On the Atlantic coast and in Wyoming there has been only a small production, but in the Pacific Coast States, especially California, the advance in the output has been remarkable. It is evident that, for some time to come, California will furnish the chief domestic supply. The production from some deposits in 1917 is expected to exceed that of 1916. It is possible, however, that some counties, Del Norte, for instance, which produced no chromite in 1916, will produce much in 1917 on account of better transportation facilities, both by land and sea. There are two main belts of production in California, one in the Klamath mountains and the Coast Range from Siskiyou county to San Luis Obispo county, and the other in the Sierra Nevada from Plumas to Tulare county. The larger output has come from the Klamath

mountains, because the orebodies there are larger and railroad transportation is more convenient.

The production in Oregon is increasing in both the Klamath and Blue mountains. The ores west of Riddle are the richest yet mined in the State, in some places assaying as high as 55% chromic oxide, and much of the ore contains about 50%. Most of the Oregon ore, however, like that of California, averages about 40% chromic oxide, and ore of that grade is commonly the basis of sale. It generally contains 38 to 45% chromic oxide, 6 to 8% silica, and 17 to 25% alumina. The largest orebody and producing mine thus far developed in Oregon is owned and operated by Collard & Moore near Holland, about 20 miles southeast of Kerby, in Josephine county. Much of the ore may be improved by concentration, and a plant of 90-ton capacity for that purpose is nearly completed. It is claimed that the ore can be concentrated to a content of 55% chromic oxide. The concentration of the lower-grade ore would give it a wider market and increase its value and the demand for it. Without concentration the Pacific Coast deposits cannot furnish a dependable supply of high-grade chrome ore, but with successful concentration industries based on high-grade ore may be attracted to the Coast. The Sawyer Tanning Co., established on tidewater at Napa, California, has had great difficulty in obtaining sufficient high-grade ore for its use. T. W. Gruetter has recently established at Kerby, Oregon, a custom-plant for concentrating black sand to win its gold and platinum. The black sand of the Klamath mountains usually contains a considerable amount of chromite, and it is believed that by adding magnetic separators to Gruetter's plant to remove the other minerals from the tailing sufficient chromite may be obtained from the black sand in chromiferous serpentine areas to make the operation financially successful.

The relation of these experiments in concentration to the problem of obtaining high-grade chrome ore on the Pacific Coast will be better understood when attention is called to the fact that by the disintegration and washing away of the weathered serpentine, in which practically all the chromite deposits occur, the heavy grains of chromite are left behind, and, consequently, the soil or surface-wash in the water-courses of serpentine areas becomes enriched by the accumulation of residual chromite. Chromite boulders and sand are therefore, as a rule, more abundant in the soil than in the solid serpentine beneath. Many prospectors finding boulders of chromite on the surface feel confident that there is a large body beneath, but a few shallow prospect holes usually give disappointing results.

\*Abstract: U. S. Geol. Surv., Bull. 666-A.

In the Atlantic States, where most of the chromite produced in this country is used, the only production is in the vicinity of Baltimore, where the chrome industry of the United States was started by the Tysons many years ago. At first bodies of chromite were quarried from the serpentine areas about Baltimore and north-eastward into Pennsylvania, but as the supply became exhausted the chromiferous residual deposits in the soil and the stream-gravel within the serpentine areas were washed for chrome-sand. A small output of chrome-sand is now obtained at Soldiers Delight, near Baltimore. This enterprise suggests the possibility of considerable expansion in the utilization of chromite sand in Maryland and Pennsylvania.

Ferro-chrome, the alloy used in making chrome-steel, is now manufactured in the United States by electro-metallurgic methods, almost wholly in the East, at the plants of the Electro Metallurgical Co. at Niagara Falls and elsewhere. The Noble Electric Steel Co. has three furnaces at Heroult, California, however, operating to full capacity producing manganese, chrome, and silica-steels. The metallurgy of chromium has apparently been so developed in the hydro-electric process as to utilize relatively low-grade ores such as are most abundant in the United States, and the further development of that process on the Pacific Coast, where water-power abounds, would greatly diminish the handicap of long transportation.

## Missouri Zinc and Lead 1915-16

The following tables give at a glance an interesting analysis of the lead and zinc ores of Missouri and their beneficiation, comparing the years 1915 and 1916, the statistics discriminating between the so-called 'soft ground' and the 'sheet ground' in the southwestern part of the State. The tables were compiled by the U. S. Geological Survey.

ZINC AND LEAD OUTPUT, SOUTHWEST MISSOURI, 1915-16

	1915	1916
<b>SOFT GROUND</b>		
Total crude ore..... short tons..	4,004,900	4,711,700
Total concentrates in crude ore..... per cent..	3.88	3.88
Lead..... do.....	.32	.28
Zinc..... do.....	3.56	3.10
Metal content of crude ore..... do.....	2.26	1.92
Lead..... do.....	.25	.22
Zinc..... do.....	2.01	1.70
Average lead content of galena concentrates..... do.....	79.2	78.0
Average lead content of lead carbonate concentrates..... do.....	58.1	55.5
Average zinc content of sphalerite concentrates..... do.....	57.7	58.1
Average zinc content of silicates and carbonates..... do.....	39.3	39.4
Average value per ton:		
Galena concentrates.....	\$48.19	\$52.09
Lead carbonate concentrates.....	\$32.56	\$31.48
Sphalerite concentrates.....	\$72.68	\$77.94
Zinc silicates and carbonates.....	\$45.00	\$50.21
<b>SHEET GROUND</b>		
Total crude ore..... short tons..	6,501,000	8,484,700
Total concentrates in crude ore..... per cent..	2.35	2.19

Galena concentrates in crude ore..... per cent..	5.47	5.60
Lead content in crude ore..... do.....	3.02	3.68
Average lead content of galena concentrates..... do.....	76.4	65.96
Average value per ton of galena concentrates.....	\$45.89	\$67.47

## Quicksilver Industry of Texas

By WM. B. PHILLIPS

\*The total value of the quicksilver produced in Texas since the beginning of the industry, in 1899, exceeds \$3,500,000. The industry has been confined to a comparatively small area in the southern part of Brewster county, about 100 miles south of Marfa, on the Southern Pacific railway. Hauling to the railroad is done by wagons, the ordinary rate being from 50 to 60c. per 100 lb. While some native quicksilver has been found, by far the greater production has been from cinnabar occurring in limestone, in a bituminous shale, and in an acid igneous rock. The larger production was formerly from the cinnabar in the limestone, but in recent years the shales have yielded the greater part. When the D-shaped retort was used in distilling the metal it was not uncommon to obtain quicksilver, a combustible gas, and oil, from the same charge, but this practice did not long survive, as the retorts required much richer ore than the Scott furnace.

The ore is crushed and charged into a brick stack provided with staggered shelves from top to bottom, heated by a wood fire, and discharging into a series of brick chambers into which all the smoke and fume is conducted. These brick chambers are the condensers. The condensing-chambers have to be made with great care, for quicksilver, although it is nearly 14 times as heavy as water, will go wherever air will go, and there are considerable losses due to the escape of the metal as a fine mist through joints and cracks. The chambers have sloping floors, and the metal drains to a small plugged opening in an iron door. It flows through this opening, at intervals, and into a cement trough communicating with a cement tank in the collecting-room. Here it is ladled into wrought-iron bottles or flasks holding 75 lb. net.

The quicksilver ores in Brewster county occur in two principal horizons, the Eagle Ford shales of the Upper Cretaceous and the limestones of the uppermost members of the Lower, or Comanchean, Cretaceous, especially the Washita limestone. In a general way the Terlingua quicksilver district is divided into two great groups by Vogel's draw, which runs from north to south. On the west side of this draw are the limestones of the Lower Cretaceous and on the east are the shales of the Upper Cretaceous. This draw marks the approximate course of a fault that has brought the Lower Cretaceous up from its normal position. There seems to be no doubt that igneous intrusions had a good deal to do with the occurrence of quicksilver ores in this district, especially at California hill and at Study butte and Maverick mountain. The richer ores have not been obtained directly from the igneous rocks nor from the limestones and shales in immediate association with them. The average content of quicksilver in the Texas ores has been higher than in the California deposits mined in recent years. The content of quicksilver in the Texas ores is from 1 to 1.10% as against 0.50 to 0.60% in California.

\*Abstract: *Manufacturers Record*.

## Cyanidation v. Flotation at Pachuca

In the latest issue of the 'Boletín Minero' published by the Department of Industry and Commerce, of Mexico, appears an article on experiments that are being made with flotation upon the silver minerals in the ores of the Pachuca y Real del Monte and the Santa Gertrudis properties, written by Simeón Ramírez, inspector of mines for the Government. He says that at the Guerrero plant belonging to the Real del Monte y Pachuca company, situated at Real del Monte near the village of Omitlán, there has been installed a flotation testing-plant employing the Minerals Separation system with a capacity of 50 tons of ore per diem. The average assay-value of the ore treated is 11 oz. silver and 0.055 oz. gold per ton, and an average recovery of more than 60% has been realized, but this percentage will be increased when the apparatus has been brought under better adjustment and when a better understanding of the proper mixtures of oils has been reached. There has been variation in the quantity of oil employed as well as variation in the speed of the agitators, air-pressure, and dilution of pulp, depending on the class of minerals contained in the slime. The average cost of concentration by this method has proved to be about \$1.57 U. S. gold per ton of ore. However, the duration of the experiments has not been sufficient to admit of safe deductions as to the cost when working on a large scale. The ores treated in the Guerrero mill come from the San Ignacio, Dolores, Cabrera, and Escobar mines, all situated in Real del Monte, and having a total output of 850 tons daily. A part of this is treated by flotation, and the rest by cyanidation when there is sufficient cyanide to be had. The following statement shows the results obtained in this plant by flotation: Recovery, by difference, silver 63.9%, gold 60%; tonnage, dry pulp sent to the machine, 1.141 tons per hr.; dilution, 4.91 parts of water to 1 part of pulp; solution shows traces of CaO.

Oils employed:	Lb. per ton
Tar-oil, Barret No. 1.....	1.319
Creosote oil, Barret No. 606.....	1.319
Pensacola pine-tar No. 80.....	0.200
Total oil used .....	2.838

Assay:	Silver, oz. per ton	Gold, oz. per ton

Tailing .....	4.32	0.016
Extraction .....	7.64	0.024

### ASSAYS OF FROTH FROM DIFFERENT COMPARTMENTS

Compartments	Silver, oz. per ton	Gold, oz. per ton
1, 2, and 3.....	160.5	0.707
4 .....	115.7	0.458
5 and 6.....	51.9	0.192
7 and 8.....	37.3	0.128
9 and 10.....	57.9	0.192
11 and 12.....	75.6	0.041

The froth in the Dorr thickener assays 422.9 oz. silver

and 1.608 oz. gold per ton. This test covered a period of 5½ hours.

The Santa Gertrudis company has three flotation machines installed close to the Santa Gertrudis mine on the slope of the hill upon which is situated the new mill and the cyanide annex. In this plant they are using Callow cells for the cleaning of the concentrate produced by 'K & K' machines. Although Minerals Separation machines were also used in the beginning, the 'K & K' is now preferred, and has given recoveries as high as 78%, with an average of 72%. These machines are simple in construction and easy to adjust and maintain.

The principal mining companies of Pachuca and El Chico are installing flotation machines and others have ordered them from the United States with the object of working out the problem of flotation for modifying their metallurgical plants. Meanwhile, they are using cyanide, the price of which is beginning to decrease. Among these new attempts may be noted the treatment of the ore sent from the Arévalo mine which has given very good results in a small Callow apparatus. Here the effect of varying quantities of oil was clearly seen in the modification of the consistence of the froth, these variations being for the purpose of obtaining the requisite persistence of froth to discharge with its load of concentrate into the concentrate-launders. This ore contains 3% lead, with an average content of 800 grammes silver (2.57 oz. per ton) of which, according to Max Kraut, 98% is readily recovered. In the ore from the Arévalo vein, which contains no lead, the recovery has been from 92.6% to 94% of the silver.

It has been observed that the ores which resist treatment by flotation in these tests have been those that contain the oxides, corresponding to the upper zone of the mine, which had formerly been abandoned as not yielding sufficient metalliferous content to pay the cost until cyanidation was introduced, but, in accordance with investigations made in the United States, it now appears possible to float these carbonates and oxides after sulphidization by soluble sulphides. On account of the difficulty in cyaniding the flotation-concentrate, due either to the fact that the oil behaves as a cyanicide or contributes in some other manner to produce a similar effect, experiments are being carried out with the object of overcoming these disadvantages. Eliminating the oil by treating the concentrate with alkaline or acid solutions or washing with water has made it appear that it is not the acid which is prejudicial but the ferrous salts formed in the concentrate itself. This indicates the necessity of further investigation in order to reach an understanding of the causes which lead to the difficulty mentioned. For the present, on account of the cost of cyanide, it appears to be profitable to extract the silver from these ores in the form of concentrate for export or for smelting locally. In order to admit of beneficiating these ores, either by cyaniding, or by floating and smelting the concentrate on the spot, it is necessary to regulate railroad traffic in order to admit of the introduction of fuels at a favorable rate.

## Tungsten Mines of Inyo County, California

Mining of tungsten near Bishop, Inyo county, California, began actively about one year ago. The ore is a low-grade scheelite associated with a garnet gangue, originating by replacement of limestone which supplied the calcium needed for the development of the garnet and epidote in the process of contact-metamorphism. No limestone, however, remains in connection with the larger bodies of ore. The granitic rocks adjoin some of the tungsten deposits, and have been profoundly altered. According to Adolph Knopf, of the U. S. Geological Survey, the metasomatic alterations of the adjoining granitic rocks occurred some time after the consolidation of the granite. The tungsten mineralization was subsequent to the intrusion both of the granite and of the monzonite of the district. The minerals included with the ore indicate that the mineralizing solutions probably entered at so high a temperature as to be in a gaseous state. These solutions were rich in silicon, aluminum, and ferric iron, were poor in sulphur, and carried tungsten, which was fixed by the calcite in the limestones as calcium tungstate (scheelite).

Owing to the garnet in the gangue the ore is rather difficult to concentrate. The average grade being treated assays close to 0.75% tungstic trioxide. The deposits occur usually in large masses of sedimentary rocks associated with the surrounding granite country-rock. The greatest depth so far reached in any of the mines is about 120 ft. below the surface and the tungsten-content seems to be increasing at this depth. Two mills are now in operation, namely, that of the Standard Tungsten Co., having a capacity of 70 tons daily, and the Tungsten Mines Co., having a capacity of about 250 tons daily. The production of scheelite concentrate is about 6000 lb. per day. At the property of the Round Valley Tungsten Co., of which Cooper Shapley is manager, a mill is being completed which will have a daily capacity of about 100 tons. A new departure from the usual milling practice is being tried at this plant, consisting in the use of a Marcy ball-mill for the fine crushing. In order to avoid sliming of the scheelite, a grate opening of  $\frac{1}{4}$  in. is used and the ore after leaving the ball-mill is screened to 10 mesh on Colorado Iron Works impact screens. By employing an excess of water in the Marcy mill, it is expected that the ore, as soon as it is crushed to pass a  $\frac{1}{4}$ -in. screen, will be flushed out and sliming avoided. The oversize from the impact screen is returned to the Marcy mill for further grinding. Mining and milling can be done cheaply because of the low-priced electric power and the accessibility of the properties to the railroad and to sources of supplies.

Besides the above-mentioned properties, another large tungsten property is now being examined with the object of installing a 1000-ton mill. Diamond-drills are to be used in the development and examination of this property, and it is probable that next year the mill will be in operation.

## Zinc Situation in Australia

\*When William Morris, the Premier of the Commonwealth, was in England he arranged a 10-year contract for the treatment of a certain tonnage of our zinc concentrate in Great Britain, and he also obtained an advance of £500,000 toward the establishment of spelter-works in Australia with a promise that the output would be purchased by the British government. What Mr. Hughes has not told us is how this half million pounds is to be allocated. The works of the Electrolytic Zinc Co. Proprietary Ltd. at Hobart, in course of erection, will call for the expenditure of £1,000,000; the Mount Lyell Co. is also considering the erection of an electrolytic plant for the treatment of the Mount Read-Rosebery ores; Gilbert Rigg, metallurgist, is investigating the subject of zinc reduction both by the retort and electrolytic methods; while a scheme for utilizing the brown coal deposits of Victoria in connection with the industry has been mooted. The need for such works is urgent, as, under present circumstances, it is impossible to find a market for the current production, notwithstanding the shipments going to the United States and to another of our allies. As a consequence large tonnages are being stacked for future treatment. It will therefore be realized that the allocation of the money obtained from the British government for this purpose is a matter of great public interest and importance, and an announcement of the government's policy in this respect should not be longer delayed. With respect to the Electrolytic Zinc Co. it may be said that the erection of the first unit capable of producing 10 to 11 tons of zinc per day is proceeding satisfactorily, and, provided no delays are experienced due to non-delivery of certain equipment under order in Great Britain, it should be in commission in August next. The experimental test-unit capable of producing 250 to 300 lb. of electrolytic zinc per day is now running, and the results confirm those obtained in America. This unit is supplying useful data, and will facilitate the earlier successful operation of the first unit. The Zinc Corporation, Ltd., has acquired a one-fifth interest in this company. David Meredith has been appointed general manager of the Amalgamated Zinc Co., in place of H. W. Gepp, who has been appointed general manager of the Electrolytic Zinc Co.

FERRO-URANIUM produced from the uranium oxide obtained as a by-product in the extraction of radium from its ores is being investigated by the Bureau of Mines. Ferro-uranium is used in making uranium steel, employed in Germany for the linings of big guns, which, it is claimed, stand up at a rate of fire so rapid that other steels fail. Work will be started on the production of sample lots of uranium steel and other special steels, for test by the Bureau of Ordnance of the War Department as to their suitability for use in guns. The work on gun-steel will also require the use of electric furnaces.

\*The Min. & Eng. Review.

## Recent Patents

1,228,183. FLOTATION OF MINERALS. Harry P. Corliss, Pittsburgh, Pa., assignor to Metals Recovery Company, New York, N. Y., a Corporation of Maine. Filed Mar. 21, 1917. Serial No. 156,491.

1. The method of effecting the concentration of minerals by flotation, which comprises adding to the mineral pulp a small amount of alpha-naphthylamin and subjecting the resulting mixture to a flotation operation; substantially as described.

2. The method of effecting the concentration of minerals by flotation, which comprises adding to the mineral pulp a small amount of alpha-naphthylamin and of oil and subjecting the resulting mixture to a flotation operation; substantially as described.

1,228,184. FLOTATION OF MINERALS. Harry P. Corliss, Pittsburgh, Pa., assignor to Metals Recovery Company, New York, N. Y., a Corporation of Maine. Filed Mar. 21, 1917. Serial No. 156,492.

1. The method of effecting the concentration of minerals by flotation, which comprises adding to the mineral pulp a small amount of nitro-naphthalene and subjecting the resulting mixture to a flotation operation; substantially as described.

2. The method of effecting the concentration of minerals by flotation, which comprises adding to the mineral pulp a small amount of nitro-naphthalene and of oil and subjecting the resulting mixture to a flotation operation; substantially as described.

1,212,334. TREATMENT OF NICKEL ORES. Frederick A. Eustis, Milton, Mass.

1. The method of recovering nickel from oxidized or silicate nickel-bearing ores, which comprises mixing the ore with a small proportion of sulfur-bearing material such as pyrite, and roasting the mixture in its raw state in a suitable furnace at such temperature and for such a time that a relatively large amount of the nickel is made soluble while a relatively small amount of the gangue is made soluble.

2. The method of recovering nickel from an oxidized or silicate nickel-iron ore, which comprises mixing the ore with a small proportion of sulfur-bearing material such as pyrite, and roasting the mixture in its raw state in a suitable furnace at such temperature and for such time that a relatively small amount of the iron is made soluble.

1,227,615. TREATMENT OF ORES. Arthur Howard Higgins, London, England, assignor to Minerals Separation Limited, London, England. Filed Nov. 14, 1913. Serial No. 800,966.

1. A process for the concentration of ores which consists in treating an ore pulp conjointly with a mineral frothing agent for the separation of metalliferous constituents by flotation and with a chemical agent that facilitates the separation of some metalliferous constituents by flotation and dissolves other constituents.

5. A process for the concentration of ores which consists in first roasting the ore and thereafter agitating it with water containing a mineral frothing agent and also a chemical agent that facilitates the separation of some metalliferous constituents by flotation and dissolves certain other constituents and thereafter precipitating the dissolved metal in such a manner as to regenerate the chemical agent.

1,228,609. PROCESS FOR MAKING INSULATING MATERIAL FROM BASIC MAGNESIUM CARBONATE AND FIBROUS SUBSTANCES. Karl Schmid, Alt-Mugeln, near Mugeln, Leipzig, Germany, assignor to the Firm of "Lipsia" Chemische Fabrik, Actien-Gesellschaft, Mugeln, Leipzig, Germany. Filed Nov. 9, 1916.

1. The process of making insulating material from basic

magnesium carbonate and fibrous substances, consisting in depositing basic magnesium carbonate on fibrous substances *in statu nascendi*.

5. The process of making insulating material consisting in depositing normal magnesium carbonate on a mass of fibrous substances suspended in a solution containing magnesium hydroxid by the reaction of a carbonate compound of ammonia therewith, thereupon filtering off the liquid and drying the remaining mass, the said normal magnesium carbonate being thereby converted into the basic magnesium carbonate.

1,228,078. RECORDING-SAMPLER. Arthur E. Truesdell, Adams, Mass. Filed June 15, 1912. Serial No. 703,803.

In a recording sampler, the combination with a chute or passageway through which the material to be sampled passes and which is provided with an opening, of a permanently-open spout communicating with said opening and adapted to receive material therefrom, a sample-receiving element rotatable in a horizontal plane beneath the delivery end of said spout and closely adjacent thereto, said element having projections extending from its periphery, automatically, operative means acting on said element and tending to rotate it forwardly, a pivoted escapement level cooperating with said projections and normally restraining said element from movement, and time-controlled electric means for periodically actuating the escapement lever to release the sample-receiving element and permit it to rotate one step forward.

1,227,867. CRUDE-OIL BURNER. John Young, New Westminster, British Columbia, Canada. Filed Jan 6, 1917.

5. A crude-oil burner, comprising in combination, an outer burner member axially bored and threaded at one end to fit an oil service pipe and therebeyond conically reduced to a cylindrical bore which at the farther end is abruptly reduced to a circular delivery outlet threaded with a screw thread, an inner burner member the outside diameter of which is at one end larger than the cylindrical bore of the outer member and at the other end has a diameter slightly less than the said cylindrical bore and intermediate of its ends is reduced below the diameter of the outer end, the reduction of the larger end being conical to correspond with the conical reduction in the bore of the outer member, the outer end of the inner member terminating a short distance from the outlet reduction of the outer member so as to leave a chambered interspace, the inner member being axially bored to a short distance from its outer end and having a series of small apertures through it at the intermediate reduced portion, and means for delivering a steam service to the bore of the inner member.

1,215,517. PROCESS FOR OBTAINING POTASH FROM POTASH-ROCKS. Frederick C. Gillen, Milwaukee, Wis., assignor to William A. Krasselt, Milwaukee, Wis.

1. The process of decomposing potash rock which consists in

mixing ground potash rock with an excess of fixed alkali hydrate, adding water to this mixture and heating it under pressure to form a solution of fixed alkali silicate and potassium aluminate, adding alkaline borate to this solution to temporarily prevent the formation of the double salt of alkali aluminum silicate, and then adding a reagent to this solution while it is under the temporary action of the alkaline borate to separate the silica therefrom and to form a solution of potassium salt and fixed alkali carbonate from which the potassium salt may be separated.

2. The process of decomposing potash rock which consists in mixing ground potash rock with an excess of fixed alkali carbonate, adding water to this mixture and heating it to form a solution of fixed alkali silicate and potassium aluminate, adding alkaline borate to prevent the formation of a double salt of alkali aluminum silicate, and then adding carbon dioxide to this solution to form a solution containing potassium carbonate, fixed alkali carbonate and alkaline borate from which the potassium carbonate may be separated.

1,228,338. CENTRIFUGAL IMPACT PULVERIZING APPARATUS. Donn O. Marks, San Francisco, Cal., assignor of one-half to Lynn S. Atkinson, Los Angeles, Cal. Filed Dec. 11, 1913.

1. In an impact pulverizing apparatus having an annular impact wall; a rotor provided with impellers pivotally connected to the rotor body at one side of their centers of gravity and extending only part of the way from their pivots to said wall, so as to leave at all times an unobstructed space between the impeller and the wall, and so that the impellers are free to swing their longitudinal axes to and fro across those radii of the rotor in which the impeller pivots are located, respectively, without touching the impeller wall; for the purpose of yieldingly taking on the material to be impelled outward for disintegrating impact with the surrounding wall.

5. In a centrifugal impact pulverizer; a rotor comprising a shaft, a head on said shaft, said head being constructed with two disks spaced apart, one above the other; centrifugally cushioned impellers pivoted between the disks; a universal joint; a bearing for the shaft; said bearing located near the lower end of the shaft and supported by the universal joint, and power applying means connected below the bearing to drive the shaft.

1,214,991. PRODUCTION OF ALUMINA AND POTASSIUM SULFATE FROM ALUNITE. Earl Blough and Thomas McIntosh, Pittsburgh, Pa., assignor to Aluminum Company of America, Pittsburgh, Pa.

1. The process of treating alunite, comprising mixing the alunite with common salt, heating the mixture whereby the salt is decomposed, dissolving out sodium sulfate and potassium sulfate from the reaction product separating the latter sulfate from the solution, heating together sodium sulfate

thus obtained and the residue from the solution, whereby the sodium sulfate is broken up, and from the residue of the latter heating dissolving out alumina as sodium aluminate.

1,227,816. AIR-LIFT-PUMP BOOSTER. Frank S. Miller, deceased, Indianapolis, Ind., by Donald S. Morris, administrator *de bonis non*, Indianapolis, Ind., assignor to William Langsenkamp, Jr., trustee. Filed May 20, 1916.

5. In combination, a closed chamber, a pipe leading from a well into such chamber, an air nozzle in such pipe below such chamber, a pipe leading from such chamber and opening into such chamber below the liquid level therein, said chamber having a restricted air outlet opening therefrom which air outlet opening communicates with the chamber at a point higher than the water level therein so as to permit a restricted escape of air while maintaining the pressure of the retained air above atmospheric pressure, and a safety valve responsive to an excessive pressure within said chamber for permitting a greater escape of air from the chamber.

1,227,831. BRIQUETTING-MACHINE. Grant W. Rigby, Pittsburgh, Pa. Filed Aug. 8, 1913.

1. A plunger mechanism for a molding machine having a reciprocating feed box for the material, comprising reciprocating plungers cooperating with said feed box and having material-receiving cavities in the end thereof, movable resisting plungers in line with said first-named plungers and having material-receiving cavities in the ends thereof, said resisting plungers being held normally stationary against pressure and having fluid cylinders therein, ejector bars within said resisting plungers for expelling the molded material from the cavities thereof, and differential piston heads connected with said bars and contained in said cylinder.

4. In a molding machine, a receptacle for containing a quantity of material considerably greater than the quantity molded at each operation, a pair of opposed molding plungers having mold-cavities at their opposing ends and arranged, when brought together, to form a mold complete in itself, means for effecting a relative movement between said plungers to effect the molding operation and the discharging operation, and means for effecting a relative movement between said receptacle and said plungers such that the molding operation takes place within said receptacle and the discharging operation takes place outside said receptacle.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## LORDSBURG, NEW MEXICO

AN OLD DISTRICT RESUMES OPERATIONS UNDER THE STIMULUS OF HIGH PRICE FOR METALS.—LARGE PRODUCTION IN 1917.—CHARACTER OF THE ORES AND GEOLOGY OF THE DISTRICT.

Among the copper producing camps of the South-west that have lately come into prominence owing to the entrance of new companies and the enlarging of operations by the established companies, Lordsburg, situated in southern Grant county, stands out prominently.

The ore of the district is in most cases of shipping-grade. There are no treatment plants in the district. Owing to the highly silicious character of the ore it is in demand at both the El Paso and Douglas smelters. Occasionally it is shipped elsewhere. The ores contain copper, gold, and silver, the first

The Lordsburg district is favored with an excellent geographical location. It is near the smelters and larger supply points. Mexican and skilled American labor may be readily obtained. The climate is mild, high, and dry. Fuel-oil is comparatively cheap, being on the main line of the Southern Pacific railroad. No labor troubles have ever arisen in the district. The people of Lordsburg stand ready to encourage and aid new mining enterprises. The proverbial camp-knocker is dying out in this section.

The production of the Lordsburg district in 1916 was about \$2,100,700 from 186,000 tons of ore shipped. The forecast of ore shipments for 1917 probably will total \$2,800,000 at the present rate of shipment.

The ore-bearing lodes of the district occur as fissures in diorite changing in places to andesite and andesite-porphry.

LORDSBURG, NEW MEXICO, AND THE 85 MINE

named predominating. I would estimate the average assay at 0.11 oz. gold, 4.07 oz. silver, and 3% copper.

During the years past the district was hindered, as many meritorious districts are in the South-west, by the lack of transportation. Up until 1915 all ore had to be hauled from 3 to 5 miles by wagon, truck, caterpillars, and other traction methods. Wet weather, bad roads, and breakdowns caused the usual delays. In 1915 the Arizona & New Mexico railroad built a spur from their main line to the 85 mine. From that time on the production of the camp was continuous and has increased monthly. The demand for the local ore has also been steady. The camp is now in a position of permanency and many new operators are taking hold of the dormant and half-dormant properties.

The largest producer in the Lordsburg district is the 85 Mining Company. The Lawrence Mining Co., operating the Bonney mine is second in output. These two companies are at present producing practically all the ore shipped from the camp. Lessees ship occasional lots but to no great extent. At the present time the Atwood mine, near the 85 property, is being unwatered and cleaned out for producing by the 85 Extension Copper Mining Co. The Valedon Mining Co., Octo Mining Co., Monte Rico Mining & Milling Co., Hecla Mining Co., and individual property holders have valuable developed and undeveloped claims in the Virginia district; none of which, however, are shipping ore. In the Pyramid district the Nellie Bly, Robert E. Lee, Last Chance, Viola, and other copper, gold, and silver claims are operated occasionally. The production from the Pyramid district, however, will be light this year.

There are at irregular intervals intrusions of the diorite into the andesite. Where these intrusions occur the ore is generally in large quantities and of high value. The fracturing of the rocks, resulting in the fissures, was followed by ascending solutions, which deposited the ores. Later, descending solutions have percolated through the silicious vein-matter depositing the mineral. This is more fully verified by the fact that the richer gold and silver ores are nearer the surface. There has been no intricate faulting where development work has opened up the lodes although a slight shearing has taken place. The dip of the veins on the 85 property, in the Virginia district, is 76° south-west and the strike is north 40° east. The width of the veins is from 5 to 50 ft. and the value ranges from \$7 to \$25 per ton. The character of the ore is oxide, chloride, and sulphide, with occasional high-grade chalcocite pockets occurring as ore-shoots in the vein.

The entire district is traversed by prominent dikes, which caused miners to first turn their attention to the district. These dikes or wall-like veins have an east-northeast trend intersecting at about Lee's peak. The dikes are highly silicious and brecciated, occurring in the porphyry and withstanding erosion.

In the western part of the field diorite-porphry is common and in the eastern exposure of andesite they are noticeable.

The Pyramid range of mountains are of Tertiary age, the characteristic country rock being andesite-porphry.

No attempts have been made in later days to treat the ore locally, although a number of experiments in flotation have been made by the 85 Mining Company. A test-plant was erected at El Paso, Texas, by J. W. Crowder, the smelter repre-

sentative, and a number of experiments made. At the present time the company is experimenting at the mine with roasting and precipitation.

A dry-mill was erected in 1915 for the treating of some low-grade lead ore found on the east side of the mineralized zone. The mill did not prove successful and was soon closed down after several months' testing was done. Save for an abandoned stamp-mill in the Pyramid camp, there are no further treatment-plants in the district.

Almost as well known as the district itself is the 85 mine and adjoining developed property owned by the 85 Mining Co., which is employing about 600 men and shipping on an average 10,000 tons of ore per month to the smelters. The 85 mine is situated three miles south-west of Lordsburg.

In 1915 the 85 Mining Co. turned in to the State Tax Commission of New Mexico a gross production value of \$762,921.78, and in 1916, \$1,456,587.29. The net value determined by the State Tax Commission for the 85 Mining Co. was \$566,613 for 1916.

The company has 12 patented claims in the Virginia district. The most extensive work, however, is being done on the '85,' '99,' Superior, Emerald, and Mohawk claims.

The ore of the 85 mine is mined by the shrinkage-stope method, with chutes every 20 ft. There are six levels, the lowest being 550 ft. from the adit-level and about 820 ft. from the surface. A main adit has been driven from the east side of the 85 mountain, a distance of 1500 ft. to the winze, from which all hoisting is done. The adit connects with the ore-bins and power-plant. Haulage is done with gasoline-locomotives, being a recent innovation here.

Mining is in progress on practically all the levels and especially the 450 and 550-ft. levels. On the 450-ft. level lateral work extends about 2000 ft. The property is connected with the Superior and other mines on the west.

The shaft has three compartments with double-deck cages. The hoist is electrically driven, Ottumwa type. Driving is done under contract, with Leyner drills. There are four electrical pumps in the mine lifting about 550 gal. of water per minute.

The company intends to continue shaft-sinking until the 950-ft. level is reached. This work is now under way.

A handsome new store building has been constructed; also a large number of houses for employees. A hotel for the single men, and a hospital, which will be used jointly between the 85 Mining Co. and the Lawrence Mining Co., are to be erected this year. Strict attention is being given the sanitation of the camp.

A. J. Interrieden, manager for the 85 Mining Co., is constantly looking out for the welfare of the employees. He has found this a paramount factor in the success of mining. In every way he has bettered the living conditions of the men and is using every means to make it an ideal camp. As a reward for his efforts there has never been any labor trouble in the camp and an efficient working force has been organized.

The 85 Mining Co. is composed of Wisconsin capitalists and business men. Arthur P. Warner and Charles H. Warner, inventors of the auto-meter, are president and secretary, respectively, of the company. B. P. Yates, president of the Berlin Machine Co., manufacturers of wood-working machinery, is vice-president, and a large interest in the company is held by James Barclay, of Hot Springs, Arkansas. J. A. Leahy, W. F. Ritter, and John Gleeson are other large owners of stock in the company.

The power-house of the 85 Mining Co. is one of the most complete and modern of any in the South-west. Power is generated by two 450-hp. Lyons Atlas Deisel-type crude-oil engines which are installed in a new steel power-house 200 by 100 ft. A 250-kva. Allis-Chalmers generator is installed to generate electricity for the mines, and air-pressure is secured from a late type Ingersoll-Rand compressor with an air displacement of 1600 cu. ft. Leyner machine-drills are used in the mine,

also Aldrich pumps. There is an auxiliary power-plant equipped with an 80-hp. Fairbanks-Morse crude-oil engine, a 6600-volt generator, and a compressor. J. H. Clark is master mechanic and G. A. Biersach is his assistant.

## PLATTEVILLE, WISCONSIN

A FALLING MARKET DISAPPOINTS HOLDERS OF ZINC AND LEAD ORE.—OUTPUT OF THE MINES IN JUNE.—NEW STRIKES AND DIAMOND-DRILL DEVELOPMENT.

Metals in general, with the exception of spelter, prospered during June. Zinc was neglected. The situation in the spelter industry could be described in few words—smelters carried unsold stocks. The softening of the spelter market toward the end of June met with a sympathetic response in the offerings for blende.

Operators viewed the situation at the close of the month with misgivings. Such as were protected in their deliveries by long-term contracts are resting quietly. Others affiliated with smelter interests, or magnetic-separating plants, operating in the field, were enabled to produce consistently. The independent joint-stock corporation, compelled to solicit bids, fared badly except in the Linden district, where nearness to reduction-plants at Mineral Point obviated excessive transportation costs. The independent producers that had facilities for raising ore to top grade have been successful in disposing of the finished product but have not always had a free field. Only when competition becomes accentuated between the large buyers, and there is a keen demand for high-grade ore for ready metal, have they been permitted to enjoy a period of real prosperity. The high cost of living leaves the large employers of mining help fearful to even hint at reductions in wages.

Lead, the last metal to respond to the War's demands, has shown increased activity, but with a price movement comparatively slow, that has given way to a market full of interest. In the Wisconsin field prices of lead ore advanced steadily during the first half of June until offerings at one time stood at \$132 per ton, base of 80% metal. Competition developed between buyers and for a time some ore came out of unexpected places, and it looked as if miners would clean-up but the nature of the pig-lead market encouraged many to hold in the belief that still better prices would be obtainable. With pig-lead almost three times as high in price as before the War, and ready metal scarce for prompt and nearby shipments, producers considered that they were safe in holding. In the midst of the hour of greatest hope came a drop to \$120 per ton.

Deliveries of ore from mines direct to reduction-plants in the field and to smelters from May 28 to June 30 were: Zinc, 48,605,000 lb.; lead, 1,190,000 lb.; and pyrite, 6,230,000 pounds. High-grade blende from refining-plants to smelters was sent out as follows: Benton, 6,968,000 lb.; Mineral Point, 5,706,000 lb.; Cuba City, 5,066,000 lb.; Linden, 342,000 lb. Total, 18,082,000 pounds.

The total recovery of mine-run product for the field from May 28 to June 30 aggregated 24,510 tons; total net deliveries out of the field to smelter, 15,430 tons. The reserve in the field at the close of June exceeded 2000 tons of raw ore at all mines; no high-grade ore was carried over; 1000 tons of lead ore and 2500 tons of pyrite.

Sales and distribution of zinc ore made during June was as follows: to Mineral Point Zinc Co., 7106 tons; Wisconsin Zinc Co., 4989 tons; Grasselli Chemical Co., 4689 tons; National Separating Co., 4691 tons; American Zinc Co., Hillsboro, Illinois, 4009 tons; Linden Zinc Co., 1465 tons; American Metal Co., 927 tons; Illinois Zinc Co., 869 tons; Mathiesen & Hegeler Zinc Co., LaSalle, Illinois, 666 tons; Lanyon Zinc Co., Joplin, Missouri, 602 tons; Benton Roasters, 551 tons; Edgar Zinc Co., 175 tons; total, 30,739 tons; the period being considered one of the best showings yet made in the Wisconsin

field and far below normal outputting capacity, there being a dearth of mining labor at all points in the field.

During June local producers of carbonate zinc ore at Highland had few offerings for this class of ore, and shipments were negligible, but the New Jersey Zinc Co., operating with new producers, increased its deliveries. The Linden district found a ready demand for its low-grade sphalerite with the Mineral Point Zinc Co. The Optimo Mining Co. had an unusually successful month. Mine No. 3 produced at the rate of 125 tons of raw concentrate per week. Mine No. 4, just opened up on the James J. Rule lease of 120 acres, discovered an extensive deposit of rich zinc ore. Drill-squads were employed on the lease all month and will continue exploration until the range has been fully prospected. The Spring-Hill Mining Co. struck new deposits on the William Ross land, and drills were kept at work proving the ground. Kletsch Bros. drilled a vein of zinc ore on the John Wasley farm and found sufficient to warrant both mine development and surface-rig. A new local mining enterprise, organized as the Super-Six Mining Co., developed a lead-ore producer on the Frank Bottoms farm. The Weigle mine, recently developed, reached, through underground workings, a new deposit of zinc ore after months of effort and recoveries are running from 10 to 12 tons of 40% zinc concentrate per shift of nine hours daily. The new producer is owned by the Milwaukee-Linden Development Co. The local magnetic-separating plant, controlled by the Zinc Concentrating Co. in New York, finished blende assaying as high as 62% zinc, calling for top prices. Official announcement was made that this plant, and that operated by the same company at Cuba City, will be doubled in capacity. Additional Dings separating-machines are to be installed. New devices for consuming gases will be a feature of the plants. The O. P. David Mining Co., in the Montfort district, drove west toward the zinc deposits found by drilling during May, and increased output was the result. Several new mining companies were organized to explore and develop new leases that are presumed to be on the trend of the main range.

In the Dodgeville district the North Survey Mining Co., in 50 working days from the time ground was first broken for foundations, built and set in operation a new 150-ton concentrator. Shipment of the first car of blende was made June 28, ore assaying over 50% zinc. The deposit occurs at a depth of 50 ft. Electric power is used throughout the mill.

Mineral Point and its vicinity, which has shown little activity in mining for many years, is being rejuvenated through the efforts of the Utt-Thorne Mining Co., which has a re-built mill in operation, a heavy pump installed, and three contiguous leases being explored. The mill makes a concentrate assaying 55% zinc. Magnetic-separation is rarely undertaken here where such a quantity of zinc is shown. Sometimes operators mix high-grade mill-feed with the low-grade to insure a better recovery.

## MEXICO

NEW LAW REGULATING OIL INDUSTRY.—PETROLEUM COMMITTEES' RECOMMENDATIONS.—OPERATION OF LAW WILL BE ALMOST EQUIVALENT TO CONFISCATION.—PRODUCTIVE CAPACITY OF THE OIL DISTRICT.

Printed copies of the first draft of the proposed law for the control and regulation of practically all phases of the oil industry in Mexico have been distributed among the interests that are to be affected. Provisions of this measure which will soon be laid before Congress are of such a drastic nature that their enforcement would mean the virtual confiscation of the landed holdings of foreign as well as native investors throughout the oil-producing region. The bill in its present form contains more than 150 printed pages. Most of these are devoted to new regulations which, if put into law, would make

the oil industry of that country so complicated as to almost prohibit it being continued, it is claimed. The proposed law is entirely separate and distinct from the taxation decree which went into effect on July 1 and which imposes a heavy burden upon oil producers. The new bill as now drawn is largely devoted to the land feature of the oil industry. As one illustration of its possible far-reaching effects it may be stated that it places the oil of the country in the same category as the metalliferous minerals, and it applies to oil development many of the regulations now contained in the mining law of that country. All land that has been leased or is owned in fee simple for the purpose of exploiting oil is required, under this proposed new law, to pay to the Government an annual tax of five pesos per hectare, which is equivalent to a tax of \$1.01 gold per acre on the land. Several of the larger oil companies own 1,000,000 to 4,000,000 acres of land and the imposition of this tax would mean an enormous annual outlay. It is estimated that approximately 25,000,000 acres of land are situated in what is known as the proved oil region bordering that part of the gulf coast around Tampico. At a tax of \$1.01 gold per acre it would mean the bringing to the Government of an annual revenue of about \$25,000,000 from this source alone; but this is not the worst and most drastic provision of the bill. Placing oil under the mining law makes all privately and publicly owned lands subject to denouncement for its possible oil wealth. In other words, if this pending measure is enacted into law, any person can go upon the land of another, whether the oil-rights upon it be already leased or not, and locate a claim of a certain size upon which to bore prospect wells, and if he happen to strike oil, which is a possible result in nearly all parts of the Tampico territory, he will have a clear title to it. It is provided, however, that the producer of the oil shall pay to the Federal government one-half of whatever royalty the original lessee may have agreed to pay the owner of the land. The new law gives to the Government a royalty on all oil that may be produced.

It is claimed that if the oil lands are made subject to denouncement by anyone who may want to go upon them and put down a well, it will mean the financial ruin of every large American and British oil-producing company now operating in that country. It is reported to be the announced purpose of President Carranza and those that occupy high positions under his administration, to cause the dividing of the oil-land holdings of the foreign investors in the Tampico region. The application of the mining law to oil development will cause a great rush of prospectors into the different fields, and instead of this enormous underground wealth being in the possession of a comparatively few concerns, it would be divided among many, and in this way the Mexicans themselves, who have up to this time neglected their opportunities for engaging in this industry, will be placed in a position to acquire, with but little cost to themselves, valuable oil holdings.

The preparation of this drastic bill was begun by a specially appointed congressional commission about six months ago and it is said to be now ready for final action of Congress. Although there has been comparatively little done in the matter of boring new wells during the past two years, a careful survey which has just been taken of the completed wells shows that they have at this time a total available output of about 365,000,000 barrels per annum. The exportations aggregate about 4,500,000 barrels per month or at the rate of about 54,000,000 barrels per annum, which leaves an underground developed supply of approximately 311,000,000 barrels. It is stated by leading oil operators here that it would be an easy matter to more than double the oil production of the Tampico territory and that this could probably be brought about within a period of six months. In fact it might be done in that many weeks as it has already been proved that it is possible to bring in wells with a daily flow of upward of 200,000 barrels each. It is not a problem of available or possible production

there, but it is one of transportation and marketing facilities which has to be met before the present export figures can be materially increased.

### LEADVILLE, COLORADO

**A GENERAL STRIKE OF UNION MEN THREATENED, AND STATE TROOPS ARE QUIETLY BEING SENT INTO THE DISTRICT TO PROTECT PROPERTY.—THE PRINCIPAL MINES CONTINUE TO WORK, THOUGH MANY MEN HAVE LEFT THE DISTRICT.**

Cloud City Miners' Union No. 33 of the International Union of Mine, Mill, and Smelter Workers, by a referendum vote taken July 3, declared in favor of a strike in the mines of the Leadville district, by 641 to 72. The strike has not yet been called, as the local organization is waiting for the arrival of a member of the executive committee of the International Union. President Carpenter and Secretary Follett, of the Cloud City Union, also stated after the result of the voting was announced that a strike would not be called until every effort to bring about a settlement with the operators had failed. This decision has tended to release the tension of the situation, although it is the general opinion that a strike will be declared, as the operators persistently refuse to make any concessions or to offer a compromise.

President Charles H. Moyer of the International Union of Mine, Mill, and Smelter Workers, predicts that a settlement will be reached before it becomes necessary to call a strike. After having been informed of the situation here showing that a majority of the union members favor a strike, he wired the following statement to the union headquarters.

"I advise and earnestly request that you return to your employment Thursday morning. Also that you elect a committee with full power to act with representatives of your international with regard to the wage demands that you have made to your employers."

This caused many men to return to work who had previously decided to draw their time-checks, or to remain away from the mines until a settlement had been reached. Nearly all of the mines continue to operate with nearly full crews. A number of Austrian miners failed to return to work, many of them having drawn their time. A few non-union men have left the district. The general opinion among the operators is that the Austrian element in the union is controlling its action, and that they have determined upon trouble that will cripple the mines. The union leaders claim that the organization has over 1000 members. If this is true, the vote taken on the strike was light, and there is no doubt that the members who did not vote were the men not favoring a strike. It was noticed that those who went to the polls were mostly foreigners, which bears out the contention of the operators that the Austrian element is in control.

A strike at this time is unpopular here among business men, mechanics, pump-men, and engineers in the mines, non-union miners, and miners generally. It is estimated that there are 2300 miners in the district, and the union leaders only claim to have 1035, many of them being smelter-men. Sentiment is not against the demands of the union, as it is conceded that under existing living costs the men are running to the limit of their wages for general expenses, and that they must have relief before long; but it is believed that action which would permanently cripple the mines of the district, throw 3000 men out of work, bring hardship to the families of as many more, possibly destroy millions of dollars worth of property, and stop the revival of mining in the Leadville district, at a time when it promises so much for the future.

On the morning of July 4, following the day of voting, one of the guards patrolling at the power-station of the Colorado Power Co., near the Yak tunnel, was fired on by a sniper hiding behind one of the buildings. The bullet pierced the hat of the guard but did him no injury. He returned the fire, but as it was dark, he could see nothing to shoot at. A search

for the sniper followed but no clue was found. On the night of July 4, a heavy charge of dynamite was exploded in an old shaft on the Sixth Street property, one of the Down Town mines that is idle. The shock broke windows in surrounding residences and store-buildings and caved the shaft.

State troops are being quietly brought into the district and stationed to protect the city light and water-plants, the smelter, and other important points.

The operators held a meeting July 6 to discuss the situation, but nothing was done that would tend to bring about a settlement. They are awaiting the action of the union, believing that should a strike be called it will prove ineffective, as many of the miners will continue to work.

New development in the district is retarded because of the pending labor trouble. A number of large enterprises that had planned to start operations about July 1 have made no attempts to proceed. On the borders of the district, however, a few companies are taking up development regardless of the situation, as it is necessary to pay higher wages to men in these out-of-the-way places than at the properties near town.

At a meeting of the union held July 9, it was decided to call the strike at noon on the 14th unless a settlement is reached in the meantime. It has also been announced that former Judge Musser, of the State Supreme Court, and Verner Z. Reed, both of Denver, have been appointed by Secretary of Labor Wilson to act as mediators in the situation. The union officials have stated their willingness to call a special meeting and further postpone the strike if the government mediators find that they need more time.

A. S. Sharp, cashier for the Leadville Water Co., and associates, have secured a long-term lease on the Houston claim in Iowa gulch, lying immediately south-east of the Ella Beeler property; and have started work cleaning out the adit.

### KENNECOTT, ALASKA

**STRIKING MINERS AT KENNECOTT MAKE ARBITRARY DEMANDS ON THE MANAGER OF THE KENNECOTT COPPER CO., WHICH DEMANDS ARE REFUSED.—FEDERAL TROOPS GUARD THE COMPANY'S PROPERTY.**

E. T. Stannard, manager for the Kennecott Copper Corporation, returned from New York on June 25. The miners, about 200 in number, that had walked out about two weeks ago, in his absence, renewed their demand for \$5.75 per day, flat wage, and gave notice through their committee that they would not even agree that that scale would obtain for any definite period. Under such an uncertain demand the management refused further to deal with the committee and immediately posted a new scale of wages effective June 16, 1917, as follows: The standard wage-scale will continue as the base-rate—that is \$4.25 per day for miners and \$3.75 for shovelers when copper is under 15c. per lb.; copper between 15 and 18c. per lb., bonus 25c. per day; copper between 18 and 21c. per lb., bonus 50c. per day; copper between 21 and 24c. per lb., bonus 75c. per day; copper between 24 and 27½c. per lb., bonus \$1 per day; copper over 27½c. per lb., bonus \$1.25 per day; settlement to be made on the average price of copper for the preceding month as given in the *Engineering and Mining Journal* quotations. Mess employees on a monthly basis will receive a bonus of \$4 per month for each 25c. change in bonus for employees on daily basis. The men agreed to return to work on this scale if the manager would take them all back. This the manager refused to do, reserving the right to reject any individual. None of the strikers have returned to work yet. The management is preparing to resume work at the mines as soon as the necessary men can be secured.

A squad of 24 United States soldiers was sent from Fort Liscum, near Valdez, to Kennecott on June 27, and are now guarding the company's property. It seems to be the general impression that plenty of men can be had within a week or two to resume operations at the mines.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—Charles Davis, of the Alaska Petroleum & Coal Co., is authority for the statement that his company will be prepared to deliver coal to the towns along the Alaska coast early this fall. A railroad from the mines to a point on Controller bay, where the coal can be picked up by barges, is now under construction. The length of the rail-haul is 25 miles.

Clark Davis, vice-president and general manager of the company, is expected at Katalla at an early date.

Katalla, July 1.

In view of the disappointing results at the Alaska Gold property, the ore running 50 to 75c. per ton below expectations, the starting of the mill on the Alaska-Juneau property adjoining has been awaited with much interest. The results to date show a very low yield of gold and compare with an average assay at Alaska Gold of \$1.19 in 1916 and \$1.15 in 1915. F. W. Bradley, president of the Alaska-Juneau company, says to the *Boston News Bureau*: "One unit of the new mill started up March 31, and in April a few additional units were started, resulting in a total crushing for the month of April of 7046 tons, having an average gold assay-value of 72.6c. per ton. In the month of May, 37,000 tons was crushed, having an average gold assay-value of 77c. per ton. For the first 10 days of June, 17,229 tons were crushed, and during the second 10 days 16,000 tons were crushed. All starting-up troubles should be gradually overcome during this summer and the mill will be in full operation by the end of the year. The milling and auxiliary surface-equipment has cost to date a total of \$2,532,027. The ore, as hauled from the mine, is first delivered for coarse crushing to a rock-house, following which is the mill proper composed of 12 units with a primary-crushing ball-mill at the head of each unit. These ball-mills were originally designed to have a capacity of 700 tons each; but it was afterward planned to push this capacity up to 1000 tons each per day, if possible; so the whole plant should have an eventual capacity of anywhere from 8400 to 12,000 tons per day. At an average daily capacity of 11,000 tons, we expect to recover 80c. per ton at a cost of between 40 and 45c. per ton."

## ARIZONA

There has been a great deal of excitement in the copper districts of Arizona the past week, every important copper producing district except Ray being affected. At Jerome an attempt to call a strike was promptly defeated and one of the I. W. W. contingent killed Orson P. McRae, shift boss in the Copper Queen mine at Bisbee, by shooting through a door. The murderer was promptly killed by deputy sheriffs.

A citizens committee and deputy sheriffs loaded over 1100 I. W. Ws. in box and cattle-cars and took them into New Mexico, where they now are guarded by Federal troops near Hermanas.

At Globe, John McBride and G. W. P. Hunt, ex-governor of Arizona, Federal mediators, appealed to President Wilson to take action to stop further deportations of strikers from Bisbee and other copper districts of Arizona. Governor Campbell wired President Wilson to send Federal troops into Arizona mining regions where strikes are in progress. These are at Clifton, Morenci, Bisbee, Jerome, and Ajo copper districts; Humboldt smelter in Yavapai county, and two districts in Mohave county.

President Wilson directed General Parker, commander of

the Southern Department, to take whatever steps were necessary to protect life and property in Arizona.

Drastic action was urged in Washington against the lawless element that seems bent on destruction of industries and crops in the West.

It is reported that the Western Union Telegraph Co. will investigate the alleged censorship of its lines leading out of Bisbee by Robert Rae, general auditor for the Copper Queen Co., and H. H. Stout, superintendent of the smelter.

## MOHAVE COUNTY

(Special Correspondence.)—A strike described by J. A. Burgess, J. L. McIver, and other competent authorities, as

MAP OF ARIZONA

second only in importance to that of the United Eastern was made last week on the Telluride property, which lies southwest of and adjoining the Tom Reed. The Telluride is controlled by J. L. McIver, one of the discoverers of the United Eastern. The vein is presumed to be an extension of the Aztec-Tom Reed vein, which is faulted near the end-line of the two properties. A drift had been advanced for 300 ft. from the shaft on the 535-ft. level along the hanging wall of a well-defined vein carrying ore intermittently. At the point of the discovery referred to the vein widened and became more solid, being composed of quartz and spar. High assays are reported. In order to explore the vein at greater depth a winze is now being sunk.

Oatman, July 10.

## CALIFORNIA

The scarcity of oil-well casing is resulting in the abandonment of various old wells for the purpose of salvaging the casing. The State Mining Bureau insists on strict compliance with its recommendations as to methods of abandoning wells so as to prevent future damage to oil lands. Each well requires special treatment and no general rules can be issued. Owners of land upon which such wells may be situated are particularly cautioned to see that the work complies with regulations, as the land is made liable under the law for the cost of remedying improper work.

Reports filed with the State Mining Bureau for the week ended July 7, show 20 new wells started, making a total of 597 since the first of the year; 16 wells were reported ready for test of water shut-off, 12 deepening or re-drilling, and two abandoned.

## CALAVERAS COUNTY

(Special Correspondence.)—The Lockwood mine, situated two and one-half miles north-east of West Point, is controlled by W. O. Pray, who is also superintendent. He is putting in a cyanide-plant. There is in the mine thousands of tons of ore in sight that averages \$7 to \$9 per ton. The Rehfus Bros. are cyaniding their tailing at the Gilbertson mine, near West Point.—The Extension of the Comet mine near Railroad Flat has started a small crew of men working two shifts.—The Black Wonder mine, situated in the Blue Mountain mining district, has started operations. It is a contact vein of slate and granite and assays well. From the Eureka Gold Mining Co. at Virginia City, Nevada, the owners bought a 60-hp. hoisting-engine and a compressor. The ore though base is high-grade.—Some Eastern capitalists, reported to be Kansas people, are sampling the Sawyer claims, which are owned by Wm. Foltz of Seattle.—The Comet mine is still working and prospects are getting better every day.—The owners of the Mason & Phillips mine have just taken out a large quantity of ore, which was hauled to the Porteous custom-mill and the bullion shipped to the San Francisco mint. Both walls of this mine are granite. It is situated in the East Belt.

The Secretary mine has just cleaned up and the mill returns went \$50 per ton.—W. O. Pray, of the Lockwood mine, has an option on the Lone Star mine two and a half miles from West Point on the Mokelumne river.—The difficulties at the Blazing Star mine, which has been in litigation for many years, have been finally adjusted and in the transaction which followed, W. O. Pray & Co. have acquired the controlling interest and now virtually own it outright. It will soon start up.—A new strike has been made by a miner, doing assessment work at the Camille, or 'Corn-Meal' mine, who uncovered a vein 14 ft. wide in slate. A moderate excitement took place locally over this development.—Wendell Phillips, of Lodi, has cleaned-up 20 tons of free-milling ore, which averaged \$30 per ton.—Judge Condon is doing assessment work at the Enterprise mine for Fred Plagemann, and has found rich sulphide ore.—At the North Star mine, situated midway between the Lockwood and the Blazing Star, the shaft has reached a depth of 57 ft. The vein is 22 in. wide with a greenstone hanging wall and a granite foot-wall. The vein consists of blue quartz with sulphide, assaying all the way from \$2 to \$110 per ton. The pay-shoot goes \$100 per ton. The present owner has had the claim for 33 years. It would seem a good proposition for some company to develop it, as the owner is unable to do the work that the mine justifies.—At the Deerfoot mine, controlled by the Rehfus Bros., they are cyaniding 500 tons of ore that runs from \$5 to \$9 per ton.

West Point, July 10.

## DEL NORTE COUNTY

(Special Correspondence.)—Chrome ore mining is becoming increasingly important in the hills back of Adams station on the Crescent City stage-road. This station is on Smith river,

just west of Gasquet. A large number of claims are leased by R. J. Rowen, M. E. Young, and Geo. S. Barton, all of Grants Pass, Oregon. About 40 openings have been started, in most of which a good showing of chrome has been made. At one place 5000 tons of ore has been developed. The claims are on what is locally called French hill. Shipments will be made by trucks to Crescent City and from there by water to San Francisco. Development work has been in progress only two months, but the ore developed warrants the commencement of shipments. The ore runs from 50 to 62% chromium oxide.

Near the Old Altaville mine, in the Low Divide district, John L. Childs and Mr. McMurray have located what is proving to be a large body of chrome. This property adjoins the Tysen Chrome and produces the highest grade of ore in the district.

PART OF CHROME REGION OF CALIFORNIA

Several auto-trucks are now hauling ore to Crescent City from this district.

W. J. Ehrman has been in Grants Pass for the past week making arrangements to get machinery hauled in to his Diamond Creek cinnabar property. There is a good road to the mine from the main stage-road, and the machinery is to be at the mine this week. This is the only developed cinnabar property in this district. Most of the ore is high-grade and it is thought that it will soon be a profitable producer.

Crescent City, July 6.

## EL DORADO COUNTY

The Noble and Farmer chrome mines are employing more than 100 men in mining and transporting chromite to the railroad, and the industry is growing as other deposits are being opened in various places.

(Special Correspondence.)—The Teddy Bear gold-quartz mine, situated on the main Mother Lode, between the old Church-Union and the Laus Padre mines, about three miles south of El Dorado railroad station, will be extensively developed by the El Dorado Exploration Co. of Seattle, under the management of John W. Cover. Five men have been working in the mine for some time, and Mr. Cover recently returned from Seattle for the purpose of pushing the development of the property. June 29 a 5-ft. vein of ore, similar in appearance to the high-grade ore of the old Church-Union mine, was found in sinking a winze, on the Teddy Bear claim, near the face of the 150-ft. cross-cut adit, at a vertical depth of about 160 ft. below the surface. The average assay-value of the ore is \$60 gold per ton. Burr Evans, consulting engineer, of Placerville, who recently visited the mine, states that the management will sink the winze to a depth of 500 ft. and open up the pay-shoot by driving north and south. After the orebody is developed a raise over the winze will be cut, thus making a shaft to the surface, and a mill of 50 tons daily capacity will be installed. A mill-test run of a dozen tons or more of the rich ore from

the vein in the winze will be made in a 5-stamp mill on Grant Busick's mine.

William Vaughn, of Georgetown, arrived at Placerville on July 9 with his six-mule team loaded with two and a half tons of high-grade chrome ore in sacks, from the Bald Mountain chrome deposit, 23 miles northeast of Placerville. Over 250 tons of ore has been shipped from this deposit, and there is a large amount still to be mined. The ore averages 63% chrome oxide and less than 3% silica.

Placerville, July 10.

#### INTO COUNTY

(Special Correspondence.)—The Darwin Development Co. is steadily increasing the development of its group of mines near Darwin and has blocked out an extensive tonnage of gold-bearing ore. A 25-ton mill, using flotation and a magnetic system of separation, is in operation and its capacity is to be increased to 75 tons daily. Late mine developments have been reported as satisfactory.

The lower tunnel of the Santa Rosa, in the White mountains, 26 miles from Keeler, has cut the orebody at a vertical depth of 400 ft. Approximately 200 veins and shoots have been cut, ranging from a few inches to 8 ft. wide. The ore contains silver and lead, and heavy shipments are being made to the Midvale smelter. Ten leases are also active. In all 55 men are employed.

Shipments from the Cerro Gordo are averaging around 50 tons daily, with much of the ore running high in silver, lead, and zinc. Shipments of slag from the old smelter-dumps continues to be profitably made. The large zinc deposit recently uncovered is stated to be developing well.

Keeler, July 10.

#### NEVADA COUNTY

(Special Correspondence.)—The Cherokee and Columbia Hill districts, near the famous old hydraulic mining camp of North Bloomfield, are active. Fully 100 men are employed in prospecting gravel deposits and tailing from pioneer hydraulic operations, and several drills are in operation. It is reported the area will be drilled to Lake City. Many of the properties in this field have been idle since the anti-hydraulic mining laws went into effect. It is understood the Guggenheims are interested in the new work, and that it is purposed to work the lower gravels with dredges.

The Roger group of quartz claims at Beauty Flat, near Washington, is being developed by the North Star Mines Co. of Grass Valley. The tunnel is advancing in promising ground and equipment will be installed. The company is understood to be considering the purchase of several placer properties in this district. The passing of the June dividend by the North Star Co., due to increased mining costs and lower gold content of the ore, has caused alarm in Grass Valley, where the regular quarterly dividends have come to be taken as a matter of course.

Dewatering of the Allison Ranch mine is proceeding and considerable work has been commenced above the 400-ft. level. Rich shoots have been exposed and the management expects to have the mill in operation shortly. The company has acquired the Benoit tract of 168 acres, adjoining the Allison Ranch on the east, and plans a thorough exploration of the area. The company, the Grass Valley Consolidated Mines, now owns 300 acres of mineral land, all to be worked from the Allison Ranch shaft. C. K. Brockington is manager.

Fifteen men are working the Goodwin placer property at You Bet, under management of Louis Gidette. It is said Austrian capitalists have purchased the property and that an effort may be made to work the gravel by hydraulicking, as other methods have not proved satisfactory.

Grass Valley, July 11.

The Golden Centre Mining Co. at Grass Valley has decided to discontinue all stopping and milling operations and to devote all energies to development of orebodies. The board of directors

has authorized the expenditure of \$200,000 to carry on this campaign of development, which includes the sinking of the shaft an additional 1000 ft. This will give the mine a total depth of 2000 feet.

#### SHASTA COUNTY

(Special Correspondence.)—At the electric smelter at Heroult, the blast-furnace will be completed by the end of the month. This furnace will have a capacity of 30 tons per day, and smelting will be done by blast as well as by electricity. Great inconvenience is caused by the inability to get electrodes for the electric process, as they are needed. The electric furnace is turning out ferro-manganese at the rate of 8 to 10 tons per day, the ore coming from Livermore and Mendocino county. Ferro-manganese is selling in New York around \$450 per ton.

The Afterthought Copper Co. at Ingot is employing 150 men. The flotation-plant will be completed by the close of the month. When that comes about the mining of ore will begin. The mine and smelter had been idle since January 1908 until recently. George L. Porter is superintendent.

At the Bell Cow mine, twelve miles west of Ono, on Arbuckle mountain, C. L. Wilson, who has the property under bond, has completed an assay-office, which with equipment has cost \$1000. The 5-stamp mill is being overhauled and will be in operating condition by the end of the month. The mill has a daily capacity of 25 tons. It will be used in making a working-test of the ore taken out in development work.

The Mountain Copper Co. keeps 20 men at work on its New Year's claim in the heart of Balaklala ground. Ore shipments are made regularly by way of Coram to the smelter at Martinez.

At the Silver King mine, four miles west of Redding, L. C. Parker has put in heavier machinery and will soon begin to sink 125 ft. deeper to open up a new level.

The Star shaft at Bully Hill has been unwatered to the 900-ft. level.—J. Barnes, operating the Summit mine west of French Gulch, has leased the Black Tom mine in the same neighborhood.

Redding, July 9.

#### TRINITY COUNTY

(Special Correspondence.)—The Trinity Star Co. is hauling lumber to the site of its new dredge to be built at Lewiston, on the Paulsen ranch. The pit for the dredge has been dug. It is 100 ft. square and 9 ft. deep. The dredge will have a wooden hull. Most of the machinery is in Redding awaiting transportation.

Redding, July 9.

#### TULARE COUNTY

(Special Correspondence.)—Approximately 72,000 tons of magnesite has been taken from mines in the district around Porterville, in Tulare county, during the six months ended June 30. The total value of this magnesite is nearly \$1,000,000, about \$160,000 being the average amount paid out monthly for magnesite both crude and calcined during the past six months. This is an increase of 200% over the output of ore for the same period last year.

From 600 to 700 men are employed at present in the various phases of the magnesite industry in this district, mining and trucking the ore, and in and around the calcining-plants and offices of the several companies operating in the Porterville district. This number of employees represents an average monthly pay-roll of about \$85,000 during the past six months.

The American Refractories Company, of Pittsburg, Pennsylvania, is the biggest buyer of magnesite in this district at present, handling approximately two-thirds of the output. Daily shipments of magnesite from Porterville now average about 400 tons. This district is at present producing from one-third to one-half the total output of magnesite in the United States.

Porterville, July 10.

#### SISKIYOU COUNTY

(Special Correspondence.)—W. R. Beal, of Happy Camp, the

owner of the Know-Nothing gold quartz mine on Know-Nothing creek, in the Salmon River district, adjacent to Happy Camp, recently took the mine under lease. It had been idle for 20 years. He is now having the 8-stamp mill overhauled and re-modeled, and has bought a compressor and will use machine-drills. The machinery is operated by water-power, which is available throughout the year. He is purchasing a large quantity of pipe and auxiliary machinery and has contracted with the Ladd Bros., of Happy Camp, to pack the machinery 7 miles to the mine from Forks of Salmon. He contemplates having the mine and mill running within six weeks. There is enough good ore in sight to operate for three years.

The Fledderman Bros., of Etna, have purchased a 3-ton Packard truck and are hauling chrome ore from their mine near Etna to the railroad. They have shipped two car-loads of ore and are loading the third car.

J. B. Nesbit and Wm. Magill, of Happy Camp, have made a road and established a camp at their copper mines on Deer Lick gulch on Indian creek. This property adjoins the Gray Eagle mines.

Harry C. Dannehower, of Philadelphia, who represents capital from that city, is investigating the copper deposits in Happy Camp district.

Dan. L. Harrington, manager for the Sullivan Machinery Co. of Chicago, has been superintending the drilling for his company on the Gray Eagle mine on Indian creek near Happy Camp. He reports that the contract for 6000 ft. of drilling on the property is about completed, and that his company has entered into a new contract for several thousand additional feet.

Harry Wilson, of Happy Camp, who has been employed at the Clear Creek copper mines, which were closed down, has left for his holding on Elk creek, which he will further develop.

While freighting a massive boiler up the Indian Creek road one of the Reichman freight teams crashed through the bridge at the George Crumpton ranch, completely demolishing the bridge, but with little damage to the freighting equipment or machinery. A new and safe bridge was constructed without delay.

Hornbrook, July 8.

#### TUOLUMNE COUNTY

O. A. Ellis, manager of the Chaparral mine, which adjoins the Buchanan mine on the south, has placed a Chile mill of novel design on his property for the purpose of testing the ore, and later to regularly operate the property if results are satisfactory. The mill weighs 5500 lb. and instead of the usual upright grinding mullers that roll around the basin, iron balls weighing 400 lb. each have been substituted. The upper part of the mill, which revolves, rests on the balls and causes them to roll around the groove at the edge of the basin of the mill, crushing the ore as it falls beneath them.

#### COLORADO

##### PARK COUNTY

(Special Correspondence.)—Because of the lateness of the opening of summer, work here has been held back more than a month. However, the good weather during June has made the resumption of mining possible and several properties are working, and many more will receive attention during the summer. C. R. Welsh and associates, who have been working the Wheeler mine since August last, are planning the installation of a compressor and air-drills. The power will be furnished by a gas-engine. A new adit is to be driven to cut the ore 140 ft. below that now opened up in No. 2 level. The ore contains from 25 to 48% lead, 2 oz. gold, and 2% copper per ton, and occurs as a fissure vein in the granite. Besides the shipping ore the mine contains a fair tonnage of milling ore. Mr. Welsh has purchased a burro train for his own use, but will be able to do considerable packing for other miners.

W. J. H. Miller is removing the ice from the adits of the

Atlantic and Pacific properties which are reported to contain a large tonnage of low-grade gold ore. Any milling ore found in these properties will be treated by the Commonwealth Mining Co. The Hock Hocking mill was started June 1 and is exceeding the expectations of the management. The new oil-engines are satisfactory. Development work at the mine is being carried well in advance of the daily mill capacity. The Commonwealth Mining Co. has again started work on the tramway, which will be completed about August 1. The mill soon will be ready and will handle custom ore in addition to that from the company mine.

Alma, July 10.

#### SAN JUAN COUNTY

The United States Smelting, Refining & Mining Exploration Co. has acquired controlling interest in the Sunnyside and Gold Prince groups of mines on Hanson's peak near Silverton. The properties are extensively developed and are reported to have blocked-out 850,000 tons of ore. The Sunnyside and No Name are the important veins, and these have been explored for a horizontal distance of 4590 feet. There are eight levels in the Sunnyside that aggregate 11,580 ft. of work. The veins run from 6 to 7 ft. wide. The ore is uniform in character and averages approximately 0.1 oz. gold, 6 oz. silver, 5½% lead, ¾% copper, and 9% zinc per ton. At Eureka, the town nearest the mines, a 500-ton flotation mill is being built. Much of the steel frame work of the old Gold Prince mill is being used in the construction of the new mill.

#### IDAHO

##### SHOSHONE COUNTY

(Special Correspondence.)—The million-dollar smelter of the Bunker Hill & Sullivan M. & C. Co., at Kellogg, was blown-in a few days ago. There was not a hitch of any kind, everything working smoothly from the start. Ingots bearing the initials of the company, 'B. H. S.,' were run from the first metal handled, and distributed among the visitors as souvenirs. The smelter has been so constructed that it may be enlarged from time to time. The next improvement will be a zinc electrolytic plant.

Spokane, July 11.

(Special Correspondence.)—On the 400-ft. level of the Giant Ledge Mining Co.'s property, on the North Fork of the Coeur d'Alene river, 25 ft. of good milling ore has been developed and the company has decided to build a mill of 150 tons capacity, to be enlarged later if a greater output can be made. Charles G. Taylor, of Murray, Idaho, is manager of the property. This mill and the development of the property was made possible by the Washington Water Power Co., of Spokane, which extended its power-line into the Murray district to supply the Guggenheim dredging operations. The power-line will pass over the ground of the Giant Ledge company and is expected to be completed by early fall.

Stockholders of the Northern Light Mining & Milling company at their annual meeting at Wallace elected directors and decided to build a 150-ton concentrator at the property on Pine creek. Plans already are being prepared and the plant will be built this summer. This is a lead-zinc property which has been well developed. It has three veins, on one of which work has been done to the 400-ft. level, where an ore-shoot 250 ft. long with an average width reported of 57 ft. The stockholders are mostly Eastern men.

The flotation-plant in course of construction for the Consolidated Interstate-Callahan company will increase the production 25%, according to an announcement by John A. Percival, the president, at Wallace. The shipment of 8000 tons monthly is expected when the flotation-plant is completed. The lead shipments for June aggregated 1000 tons, the largest in the history of the mine. It is believed this output can be maintained. When the flotation-plant is in service the zinc output is expected to be 7000 tons monthly.

Lead producers of the Coeur d'Alene have agreed to divert one-sixth of their July output to the Government. A meeting was held in response to a call issued by Harry L. Day, member of the lead committee, at the request of Chairman Crane. Nearly all big producers of the district were present. Spokane, July 2.

## MONTANA

### SILVER BOW COUNTY

Press dispatches indicate that the mining industry at Butte is almost at a standstill, thousands of men being idle as a result of the strike of electricians, who are demanding of the Montana Power Co. a higher scale of wages. The power company has made concessions and there is hope that the difficulties soon will be settled.

The Butte *Miner* states that letters have been received from a high official of the American Federation of Labor urging a speedy termination of the strike and that the men return peaceably to work, for there is good reason to believe that if this is not done the Federal authorities at Washington will conscript the strikers, take control of the copper mines, and require the miners to work for a much lower rate of wages than they have ever received at Butte. It is argued that the Government would not be willing to pay men that were thus drafted to serve at their occupation as miners a much higher rate of wages than is paid men in the trenches, where the risks are infinitely greater. Foreseeing that the liberal wages now paid in the Butte district are in jeopardy, the high officials of organized labor are urging the men to take a common-sense view of the situation, to cease agitation, and hold on to their jobs.

As a result of a disagreement between the striking miners and electricians at Butte, it was proposed to form a new union. At a meeting of the Metal Mine Workers' Union, held July 12, a resolution was passed without a dissenting vote, to the effect that one delegate for every 500 men in the union be sent to Denver not later than August 1 for the purpose of meeting to form an international union.

## NEVADA

### ESMERALDA COUNTY

(Special Correspondence).—The east cross-cut from the 320-ft. level of the Cracker Jack mine has entered what appears to be the Columbia Mountain fault-vein 700 ft. from the shaft. The rock is badly crushed and appears to be a widely shattered zone. It is stated to assay around \$7 gold per ton. Cross-cutting continues in expectation of intersecting the Rabbit Trail vein.

The main north drift from the 880-ft. level of the Jumbo Junior is being extended through the leased section of the Kewanas mine to connect with the main workings of the latter. The orebody has been exposed for about 150 ft., ranging from 1 to 3 ft. of good ore. The latest assays average \$56 per ton. It is planned to make a small shipment.

The Red Hill Florence Co. is developing the Florence vein on the 500-ft. level and reports encouraging results. Work is also proceeding from several points higher. Negotiations for control of the Florence mine continue and most of the large stockholders and creditors are said to have signified their approval of the project.

The Goldfield Consolidated Co. is using the aerial-tramway between the tailing-pond and mill and is treating some of the old mill material in its cyanide-plant. Developments are now largely confined to the deeper levels for the purpose of augmenting the reserves of copper-gold ore. Recent work in the deep levels of the Laguna and Mohawk are reported to be particularly satisfactory. The company has not yet begun to treat ore from the Atlanta, although arrangements to this end were made several months ago.

Goldfield, July 12.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

H. R. WAGNER has returned from Chile to New York.  
F. LE ROI THURMOND has opened an assay-office at Anchorage, Alaska.

L. A. PARSONS has returned from Cobalt to Copper Cliff, Ontario.

JOHN H. BANKS has returned to New York from Jerome, Arizona.

MILTON A. ALLEN is now with the Arizona Bureau of Mines at Tucson.

HOMER L. CARR, of New York, is visiting the mining districts of California.

A. O. GATES has obtained a commission in the U. S. Naval Reserve Forces.

J. B. TYRELL now represents the Consolidated Mines Selection Co. in Canada.

E. B. HOPKINS, geologist, has gone to Mexico for the Associated Geological Engineers.

S. E. WOODWORTH has become an ensign in the Navy and is undergoing training at Annapolis.

GEORGE J. YOUNG, professor of metallurgy in the Colorado School of Mines, is in Tuolumne county.

E. C. GAMBLE and W. S. STEWART of Oakland, California, have been examining mines in Mariposa county.

S. C. DICKINSON is now safety engineer with the Arizona State Bureau of Mines, with headquarters at Tucson.

F. C. FREY, manager of the Redjang Lebong mines, in Sumatra, has returned to Reno, Nevada, on a holiday.

RICHARD B. MOORE, of the U. S. Bureau of Mines, passed through San Francisco on his way from Denver to Tucson.

ARTHUR C. TERRILL has returned to Lawrence, Kansas, from inspection of Osage City coal mines and Blue Rapids gypsum mines.

WALTER R. VIDLER, of Cripple Creek, has been in the Llano-Burnet district of Texas, and at Bowie, Arizona, on professional business.

F. J. HOENIGMANN and W. G. FARNLACHER have returned to San Francisco from Nevada and Utah, respectively, to do military service.

H. J. SHEAFE, superintendent of the Globe Mines, California, has obtained a commission as captain in the Engineer Officers Reserve Corps.

FOREST RUSHERFORD has resigned as general superintendent of reduction works for the Copper Queen Co. at Douglas, Arizona, and will open an office as consulting metallurgical engineer after a summer's rest. His present address is Pueblo, Colorado.

## Obituary

FRANK M. MURPHY, a prominent mine and railroad operator, of Arizona, died at Prescott, on June 24, at the age of 62 years. For many years Mr. Murphy had been identified with the development of northern Arizona. In 1887 he succeeded in interesting "Diamond Jo" Reynolds in the Congress mine, near Wickenburg, and for years Mr. Murphy was the successful manager of that famous gold mine. It was largely through his efforts that the Santa Fe built its connecting line between Ash Fork and Phoenix, and was for a long time its manager, and secured the building of a number of important branches of the road. He also established the Prescott National Bank, and was prominent in many other important business enterprises, including the extensive operation of several groups of mines in the Bradshaw mountains and elsewhere in Arizona. He was a man of recognized business ability and integrity. His loss will be sincerely regretted by all who knew him.

## Eastern Metal Market

New York, July 11.

Decided weakness is manifested in nearly every metal, except tin which is higher. Continued uncertainty as to purchases by the Government and the Allies is the main cause.

Copper is stagnant and weaker.

Tin is higher but not specially active.

Lead is dull, uncertain, and lower.

Zinc is almost paralyzed and is again lower.

Antimony has declined and the demand is very poor.

Aluminum is a little lower, but still inactive.

The chief market influence in the steel-world is the expectation that some form of price-regulation, either by the Government or by producers under Government sanction, will be effected. A dictatorship of steel manufacture and distribution seems less a possibility today than last week. Estimates, by steel-makers, of the Government and Allies' total buying of steel-products, expressed in terms of ingots, approximate 12,000,000 tons for the coming year, or about 30% of the country's present steel-production. Government use of plates and shapes is expected to reach 40 or 50%. New business is less than in two years and export dealings are being held up by Washington. The actual effect of the embargo, set for July 15, in the domestic market, is not expected to be important, since exports of the principal steel-products to neutrals have been small.

### COPPER

The market is stagnant and weaker. Yesterday, after a week or so of easy tendencies, decided softness was discernible, and both Lake and electrolytic were again lower at 30.75c., New York. One explanation of the fall to lower levels is that, in the absence of business, some sellers may have become tired of sitting still and may be offering at concessions. Whether this is coming from first or second-hands is difficult to decide. One reason for this change in prices and sentiment is attributed to the possible conviction on the part of some that future prices for copper, purchased by the Government and its Allies, will be lower than 25c. per pound, perhaps as low as cost-price plus a reasonable profit. The continued haggling at Washington on this subject may result in a dead-lock, in which case the Government would take a hand and have its own way and the copper producers would be deprived of the expected cinch. Added to this consideration is the reported rejection by the Government of the proposal of the aluminum producers to furnish that metal at 27c. per lb. While the market is without features, there is at the same time much less gossip. Strikes among metal miners and producers continue disturbing. Quotations for later positions have also eased off about  $\frac{1}{2}$ c. per lb. to 29.50c. for the third quarter, and to 28.50c. for the fourth quarter. There are no changes in the London quotations as reported last week.

### TIN

The tin market, while stronger, has developed some peculiar features. Demand has been varied and spotty during the past week. While inquiry for futures one day has been good, with that for spot poor, the next day the contrary has been the case, with futures neglected and nearby metal in demand. For instance, on July 5 there was a good future demand amounting to 200 to 250 tons, which ended in business, but spot delivery was dull. On the 10th, however, futures were neglected, with nearby inquiry for tin afloat resulting in fair sales, but the spot market was quiet. Prices have consistently advanced the past week to 63c., New York, yesterday for spot Straits, an increase of 1c. per lb. since July 2. This has been due largely to the fact that stocks of spot Straits are now light and

it is easier to buy 5 tons than 25 tons. The cable situation has continued to be disturbing. With hardly an exception London cables have been delayed almost daily, hampering business here decidedly. The weekly complaint regarding Government indecision as to taxes and other matters is also a factor, and these two elements have almost caused a halt in general business. Tin arrivals to July 10 inclusive have been 700 tons, with the quantity afloat at 4354 tons. The London market has advanced £3 over that of July 2, spot Straits being quoted at £247 there yesterday.

### LEAD

Lead is again lower and yesterday was quoted at 11c., St. Louis, or 11.12 $\frac{1}{2}$ c., New York. Demand has declined almost daily and lower prices have consequently resulted. Some lots to large buyers have been offered at under 11c., St. Louis. There is very little if any difference now between the trust and the outside market, the quotation of the former still being unchanged at 11c., New York. It is reported that some of the large producers have no metal to sell for July, while others have, and the situation is unusual. The attitude of the Government is a disturbing feature, and while more orders from this source are expected, developments may be such in the near future as to cause a decided reaction further downward.

### ZINC

The entire market is extremely dull and is weakening. Demand is almost nothing and sales scarce. Attempts are being made to hold the quotation for early delivery at not much under 9c., St. Louis, but it is believed that some quiet scalping has been done and that sales have been made at 8.87 $\frac{1}{2}$ c., St. Louis, or 9.12 $\frac{1}{2}$ c., New York. At these prices, however, some producers are certain to be operating at a loss and many may have to shut-down soon entirely. Some have already done so, giving needed repairs as the excuse. Futures continue a little higher than early deliveries, perhaps  $\frac{1}{4}$ c. higher, but demand is quiet and there is not much inclination to sell for this position. It is not unlikely that labor troubles will be an important factor in the not distant future. Labor difficulties of great seriousness are reported from the Butte and Lake Superior districts. No details are yet available as to the reported purchase by the Government of 11,000 tons of high-grade spelter at 13.50c. per lb. Some credit it; others believe it is not a fact. Continued uncertainty as to Government needs and prices exert a demoralizing influence and the prospect is not bright. According to statistics completed by W. R. Ingalls of the *Engineering and Mining Journal*, the production of spelter in the last quarter of 1916 was 189,572 net tons, the largest of any quarter since or before the War, the largest just before the War having been 92,816 tons in the second quarter of 1914. His classification of the 1916 consumption of spelter shows 207,849 tons as consumed for galvanizing, 175,435 tons for brass, 40,053 tons for sheet zinc, with the balance of a total of 450,304 tons for other purposes.

### ANTIMONY

The antimony market is not only dull but lifeless. Demand is so slack that quotations have fallen to 17c. to 17.50c., New York, for Chinese and Japanese grades.

### ALUMINUM

No. 1 virgin metal, 98 to 99% pure, is a little lower because of the slack demand and for early delivery is quoted at 57c. to 59c., New York. It is reported that the Government has rejected the producers' proposal to furnish aluminum at 27.50c. per lb.—the 10-year average price plus 2c. per pound.

## Company Reports

### TONOPAH MINING COMPANY OF NEVADA

The fifteenth annual report of the Tonopah Mining Co. of Nevada for the year ended December 31, 1916, states that a total of 81,782 tons of ore was milled, containing 15,636 oz. of gold and 1,387,557 oz. of silver, of a gross value of \$1,279,157.86. The average recovery of the value was 94.2% of the gold and 90.3% of the silver. The recovery of value based on net smelter returns was 90.1%. In October the crusher-plant was almost totally destroyed by fire. The plant was re-built upon a less elaborate plan, but sufficient to meet present requirements. In the meantime the crushing-plant of the Western Ore Company at Millers was used where all the ore was crushed and sent to the mill. By this arrangement little time was lost. Operating statistics follow:

#### OPERATING STATISTICS

Tons of ore mined.....	74,991
Tons of ore shipped from dump.....	5,542
Tons of ore treated at Desert mill.....	81,782

#### COSTS PER TON

The average cost to mine and mill the ore and market the products for the past year was as follows:

Mining costs and costs of handling dump ore.....	\$ 4.61
Milling costs .....	3.16
Freight on ore milled .....	0.72
Marketing mill products .....	0.22

Total costs per ton .....	\$ 8.71
Metal losses in milling and refining.....	1.34
Profit per ton .....	5.60

Average gross value of ore milled.....	\$15.65
--	---------

### SUBSIDIARY COMPANIES OF THE TONOPAH MINING COMPANY OF NEVADA

#### TONOPAH PLACERS COMPANY

##### Operating at Breckenridge, Colorado

The three dredges were put in operation during the month of March, and continued in operation until the end of December, at which time the two large dredges were closed down, and the smaller dredge continued in operation until the latter part of January 1917. The dredges were closed down on account of the winter weather and for necessary repairs. An indebtedness of \$56,000 to the Tonopah Mining Co. was paid off during the year 1916. No. 2 dredge was operating during the whole season upon property owned by the Farncomb Hill Gold Dredging Co., under a contract with that company. The net earnings of the dredge, while on this property, will be divided equally between the Farncomb Hill Gold Dredging Co. and the Tonopah Placers Company.

#### THE MANDY MINING COMPANY

##### Operating in Manitoba, Canada

A property located in the Province of Manitoba, Canada, was acquired during the past year, and the Mandy Mining Co. was organized to own and operate it. The Tonopah Canadian Mines Co. owns 85% of the stock of the Mandy Mining Co. About 20,000 tons of high-grade copper ore has been developed on this property, and shipments of this ore to the smelters are being made.

#### THE EDEN MINING COMPANY

##### Operating in Nicaragua

The electric-power plant of the Tunkuy Transportation & Power Co. was completed and put into operation during the month of May, and has been in continuous operation since that time.

The mill made its first run on ore March 1, 1917.

In the month of June, J. L. Phillips resigned as general superintendent, and Robert Hawxhurst, Jr., was appointed as his successor.

#### TONOPAH NICARAGUA COMPANY

##### Operating in Nicaragua

A property known as the Santa Rita Mines, located about thirty miles from the property of the Eden Mining Co. in Nicaragua, was purchased during the past year for \$10,000, and the Tonopah Nicaragua Co. was organized to own and operate this property. A force of men is now engaged in clearing the property and in development work, and it is expected that shipment of the products from this property will be made during 1917. The Tonopah Mining Co. owns about 92% of the stock of this company.

#### THE TONOPAH CANADIAN MINES COMPANY AND BRUTUS MINING COMPANY

Mining claims adjoining those of the Mandy Mining Co. were acquired and located during the past year, and the Tonopah Canadian Mines Co., and the Brutus Mining Co., which is controlled by Tonopah Canadian Mines Co., were organized to own and operate these properties. The Tonopah Mining Co. owns about 92% of the stock of the Tonopah Canadian Mines Company.

The option upon the property of the Mispah Extension Co. was extended in January 1917, for one year, and work is being continued upon the property, but no decision has as yet been made as to its acquisition.

#### THE GREAT BOULDER PROPRIETARY GOLD MINES, LTD.

The annual report of the Great Boulder Proprietary Mines, Ltd., in Western Australia, for the year ended December 31, 1916, shows the following:

	£	s.	d.
Expenses in opening up 120,900 tons of ore.....	7,574	6	10
Expense stoping 175,787 tons of ore.....	112,271	2	8
Sulphide mill expense, 175,787 tons of ore.....	73,912	17	2
Cyanide mill expense, 175,787 tons.....	33,376	17	8
Residue re-treatment, 206,443 tons.....	14,958	13	1
General charges .....	8,917	6	3
Sundries .....	5,418	18	2
Total expense .....	256,430	1	10
Gold realized .....	442,629	18	6
In process of realization .....	81,767	7	8
	524,397	6	2
Less cost of minting.....	916	3	8
	523,481	2	6
Sundry receipts .....	101	9	7
	523,582	12	1

The total cost per ton of ore treated in 1916 was 27s.10d.

Extensive diamond-drilling operations were carried on during the year, a total of 54,921 ft., equivalent to 10.401 miles having been bored.

There is estimated to be still available in the mine 372,791 long tons, having a total gross value of 271,706 oz., equivalent to about \$5,434,000.

Labor shortage was responsible for less development having been done than had been planned. With a view to acquiring another property, many mines offered were examined, but, so far, none was found sufficiently promising to warrant development. Dividends paid during the year were as follows:

June 22.....	£65,625
Sept. 29.....	65,625
Dec. 23.....	65,625

A fourth dividend of £65,625 was paid March 24, 1917, making a total within a year of £262,500.

## Recent Publications

THE PLEISTOCENE CITRONELLE FORMATION OF THE GULF COASTAL PLAIN AND ITS FLORA. By George Charlton Matson and Edward Wilber Berry. Professional Paper No. 98-L. U. S. Geological Survey. Pp. 41. Ill., Index.

THE INORGANIC CONSTITUENTS OF MARINE INVERTEBRATES. By Frank Wigglesworth Clarke and Walter Calhoun Wheeler. Professional Paper No. 102. U. S. Geological Survey. Pp. 56. Washington, 1917.

THE OREGON BASIN GAS AND OIL FIELD OF PARK COUNTY, WYOMING. By Victor Ziegler. Bulletin No. 15 of the office of the State Geologist of Wyoming. Pp. 32. Ill. and maps. Cheyenne, Wyoming, 1917.

This bulletin describes the location, physiography, and geology of the oil-gas fields of Park county, together with a brief description of numerous wells.

A BIBLIOGRAPHY OF THE GEOLOGY AND MINING INTERESTS OF THE BLACK HILLS REGION. By C. C. O'Harra. Issued by the South Dakota School of Mines, as Bulletin No. 11. Pp. 216, with index and map. Rapid City, 1917.

This will prove to be a useful volume to those who are in search of information relating to the greatly varied mineral resources of that wonderful mineral province known as the Black Hills.

NOTES ON THE GEOLOGY AND IRON ORES OF THE CUYUNA DISTRICT OF MINNESOTA. By E. C. Harder and W. A. Johnston. Bulletin 660-A. U. S. Geological Survey, prepared in co-operation with the Minnesota Geological Survey. Pp. 26. Maps. Washington, 1917.

Describes the general geology of Minnesota and more particularly the rocks and geology of the iron deposits of the Cuyuna district.

GEOLOGY AND MINERAL RESOURCES OF THE REEFTON SUBDIVISION, THE WESTPORT AND NORTH WESTLAND DIVISIONS OF NEW ZEALAND. By J. Henderson. Bulletin 18 (new series) of the New Zealand Geological Survey. Pp. 232. Ill., maps, and index. Wellington, N. Z., 1917.

This publication is a general geological treatise on the ore deposits, geology, and mining industry in the several districts mentioned in the title.

TWENTY-FIFTH ANNUAL REPORT OF THE ONTARIO BUREAU OF MINES. Pp. 311. Ill., maps, index. Toronto, 1916.

This publication reviews the mineral industry of Ontario in 1916, devotes a chapter to mining accidents, describes the mines of Ontario, giving a detailed geological description of numerous deposits. One chapter is devoted to a scientific study of certain minerals of the Cobalt district. The metallurgy of the ores is also described with flow-sheets of some of the mills.

The following publications have recently been issued by the United States Bureau of Mines, Washington, D. C.:

BULLETIN 124. Sandstone quarrying in the United States, by Oliver Bowles. 1917. 143 pp., 6 pl., 19 fig.

TECHNICAL PAPER 82. Oxygen mine-rescue apparatus and physiological effects on users, by Yandell Henderson and James W. Paul. 1917. 106 pp., 5 pl., 6 fig.

TECHNICAL PAPER 135. Bibliography of recent literature on flotation of ores, January to June, 1916, compiled by D. A. Lyon, O. C. Ralston, F. B. Laney, and R. S. Lewis. 1917. 20 pp.

TECHNICAL PAPER 140. The primary volatile products of the carbonization of coal, by G. B. Taylor and H. C. Porter. 1916. 59 pp., 1 pl., 25 fig.

TECHNICAL PAPER 143. The ores of copper, lead, gold, and silver, by C. H. Fulton. 1916. 45 pp.

TECHNICAL PAPER 160. The determination of nitrogen in substances used in explosives, by W. C. Cope and G. B. Taylor. 1917. 46 pp., 1 pl., 4 fig.

TECHNICAL PAPER 166. Motor gasoline; properties, laboratory tests, and practical specifications, by E. W. Dean. 1917. 27 pp.

## Book Reviews

THE EFFICIENT PURCHASE AND UTILIZATION OF MINE SUPPLIES. By Herbert N. Stronck. Pp. 97. Ill. diagrammatically. John Wiley & Sons, New York and London. For sale by the MINING AND SCIENTIFIC PRESS.

This little book will be found most useful to mine superintendents who wish to handle their mine-supplies in a methodical and economical manner. It includes chapters on the purchasing department; the receiving and testing department; the stores system with accurate accounting; the issuing system; reports on consumption of supplies, and methods of preventing waste. There are numerous styles of blank forms for all purposes connected with the warehouse and stock-rooms of a mine, and many valuable suggestions to the store-keeper and accountant.

STEAM TURBINES. By James Ambrose Moyer. Third Edition. Pp. 460 and index. Ill. John Wiley & Sons, New York and London. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$3.50.

This excellent work is a compendium for power users, being a practical and theoretical treatise for engineers and students. It reviews completely the recent improvements in the economy of steam-turbines, and as the author says: The low cost of power where fuel is cheap makes the large turbine-electric generating-plant almost an unrivaled competitor of water-power for metallurgical purposes. Many changes have been made in some departments of the book and it is in every sense up-to-date. All who contemplate large power installations should secure this book in order to be fully informed in the most modern practice in the generation of power for any purpose whatsoever. In an appendix is a series of questions, with answers, for the student who soon may have these very questions presented to him in actual practice.

PROPERTIES OF THE CALCIUM SILICATES AND CALCIUM ALUMINATES OCCURRING IN NORMAL PORTLAND CEMENT. Technologic Paper of the Bureau of Standards, No. 78. By P. H. Bates and A. A. Klein. Pp. 38, ill., has no index. Washington, D. C., 1917.

This pamphlet is replete with new data concerning the characteristics of cement, revealing by microscopic investigation the constitution of the clinker obtained from different mixes, and the resultant compounds after wetting, and setting in briquettes. It throws light on the conditions that give strength and weakness to cements, and should be carefully studied by engineers. The conclusions are succinctly set forth in a summary which shows among other things that tri-calcium silicate has all the important properties of portland cement, especially those of the rate of setting and strength developed. It also shows that plaster of paris when added to any of the compounds or mixtures studied generally increased the strength at all periods. The authors state that the ideal cement should apparently have an excess of di-calcium silicate, which would give a moderately dense hydrated material that will gain strength with aging of the concrete.

# INDUSTRIAL PROGRESS

## Use of the Cement-Gun at the Anaconda Mine

For the following description of the cement-gun we are indebted to C. H. Abeling, E. M., of Butte, Montana.

The ores of the Butte district carry a high sulphur content. Fires occur, at times, from spontaneous combustion and from other causes. Areas of smoldering ore, though they be relatively small, emit sulphur fumes and gases that are dense

enough in the confined spaces of drifts and stopes to prohibit any mining operations near these areas.

A number of mines operated by the A. C. M. Co. are connected in their underground workings. The fumes from a small area of smoldering ground will, therefore, penetrate to the workings of several mines.

The only feasible way thus far found to overcome these fires is first to seal the affected area from other workings. This is

FIG. 1

FIG. 2

FIG. 3

FIG. 4

accomplished by building cement-bulkheads at all openings leading from the burning area. Working in such a small space, it is next to impossible to place this cement by hand in a short time. When in place it is found to be porous and cracked, due to shrinking and settling. Sealing with the cement-gun later is accomplished, in one-fifth the time required by hand-work.

The cement-gun has solved this difficulty and made possible the construction of bulkheads under conditions where hand-placing would have been impossible. These bulkheads are absolutely tight and were constructed in record time.

The cement-gun was first used in February 1917, and in the construction of all bulkheads since that date the cement-gun has been used wholly or in part. The limited number of guns obtainable on short notice prohibit the building of all the bulkheads with the gun.

In February 1917 fumes from an area in the Leonard mine necessitated the construction of several cement-bulkheads. Other emergency bulkheads were constructed beyond these points closer to the shaft; these being built as a precautionary measure in case fire or fumes should enter the area between the two bulkheads.

Views No. 3 and 4 show the upper and lower parts of a large bulkhead built on the 2000-ft. level of the Leonard mine. This bulkhead is over 13 ft. wide, 18 ft. high, and 5 ft. thick, and contains over 1200 cu. ft. of concrete.

Six inexperienced operators of the cement-gun constructed this bulkhead in 36 hours. The men were distributed as follows: One man operating the gun, one man operating the nozzle, two men mixing, and two men screening sand. All material was delivered at the gun.

The longitudinal-section, A, and elevation, B, of this bulkhead gives a clear idea of its construction. As the cement was shot into place by the cement-gun, rock was placed in the form to aid in its rapid construction.

The cement-gun plays its most important part in the joining of the bulkhead to the back of the drift or stope. The finished work shows that the mixture of sand and cement has been shot into every crack and fold of the rock until it can hardly be distinguished from the rock itself. In some instances, on account of fumes, it was necessary for the nozzle-man to wear a compressed-air hood.

View No. 2 is an emergency-bulkhead on the 2000-ft. level of the Leonard mine. This bulkhead is approximately 9 ft. 8 in. high, 9 ft. wide, and 4 ft. 6 in. thick. The passageway is 6 ft. high and 4 ft. wide. A heavy sheet-iron door is provided to place over this opening on short notice. The upper half of two of these bulkheads were completed in 8 hours. This included moving, connecting-up of machine, and laying of the mixing-floor.

In preparing the ground for these bulkheads, no other work than picking out the loose rock on the bottom, sides, and back was done. The loose rock in the bottom extended from 16 to 24 in. below the track-level.

In some cases there were large loose boulders in the back which it was not feasible to remove. They were held in place by stulls and cement was shot in the crevices between them. When this had set, the stulls were removed and the bulkheads built from the floor up to meet them.

In some cases, after the completion of these emergency-bulkheads, cement was shot on the entire back and sides of the drift on either side of the bulkhead for a distance of 16 to 18 ft. in length. This sealed all seams that were likely to by-pass fumes around the bulkhead. Heavy blows will not cause this coating to shiver off nor to show any line of cleavage. The only result is a powdering of the cement directly under the hammer-head. Immediately above the passageway in these bulkheads, pipes were cemented in to allow of passing air, water, and electric-wire through the bulkhead.

View No. 1 shows a 50-ft. approach to the 2200-v. transformer-station on the 1200-ft. level of the Leonard mine, pro-

tected with gunite placed with the cement-gun. The object of this work was to fire-proof that section from possible fire at the transformers.

The Anaconda Copper Mining Co. is contemplating the construction of 1500 lineal feet of this work in the near future. This is in drifts through which high-tension electric-cables are installed.

Preparatory to guniting this approach, mine-lagging was placed behind the posts and on top of the caps. On this was placed horizontally, No. 24-gauge, AAA grade, flat herringbone steel expanded-lath. The ends were sprung outward and bent to fit the contour of the posts. On this lath was shot 1 to 1½ in. of cement. In this way every crack, however small, on any flat surface or in any angle has been thoroughly sealed by the cement-gun.

Considering that the nozzle-man was obliged to stand at from two to three feet from the wall upon which the cement was being placed, the finished surface is remarkably smooth and presents a very neat appearance.

On account of the dimensions of the N-1 gun, allowing of its being lowered on the cage without being dismantled, and of its easy passage into drifts and cross-cuts, this size was adopted.

The wheels and trunnions were removed and the machine fastened to a sheet-iron plate mounted on an ordinary mine-truck.

The Anaconda Copper Mining Co. has six of the N-1 size cement-guns and two more are on the way from the factory. It is the intention to equip each of its mines with a sufficient number of these guns adequately to take care of all bulkhead-construction.

The data and views used in this article were obtained through the courtesy of C. L. Berrien, assistant general superintendent of mines, Anaconda Copper Mining Company.

## Smelter Stacks

The metal-stacks of smelters are subjected to particularly severe conditions. It is known that chemical activity increases rapidly at high temperatures and it is a common sight to see smelter stacks rusty. Paints have been sought to protect these surfaces from rust, as the cost of replacement is high. Smelter stacks are subjected to high temperatures, from 600 to 800° F., and to severe conditions due to the fumes incident to smelting. Oronite enamel-paint has been successfully used by some of the large copper-smelting companies in Arizona and Nevada and has proved its worth. Oronite is made by the Standard Oil Company.

## Commercial Paragraphs

The LIDGEWOOD MANUFACTURING Co., of 96 Liberty street, New York, has issued a new bulletin, No. 20, descriptive of its electric hoists. These machines are made in a great variety of shapes and sizes, from small portable hoists, mounted on a 4-wheeled truck, to large hoisting machines designed for mines. It also includes hoists for quarries, ships, buildings, and for other purposes, such machines being designed to meet the requirements of their particular use. The catalogue can be secured by application to the manufacturers.

The WESTINGHOUSE ELECTRIC & MANUFACTURING Co., of East Pittsburgh, Pennsylvania, has issued illustrated folders and sheets descriptive of the following electric or electrically operated devices: A new recording-demand watt-hour meter; crane protective panels; headstock equipments for wood-working lathes; harmonic analyzers; outdoor metering equipments; electric-speed indicators; type HB overhead relays; portable fault localizers (DS-959); potentiometers (DS-990), for hot spot temperature measurement; synchronous booster converters; and motors for paper-finishing mills.

## TABLE OF CONTENTS

EDITORIAL		Page.
STEEL ON THE PACIFIC COAST.....		112
High price of pig-iron bringing iron industry to the West; Merrimac Steel & Smelting Co. constructing plant in Nevada; Crocker-Thane syndicate financing large steel industry in State of Washington. M. & S. P., July 28, 1917.		
SAMPLING LARGE LOW-GRADE OREBODIES.....		113
Summary of opinions by Messrs. Loring, Webber, Parsons, Burch, Parker, Leggett, and others; discrepancies between sampling and exploitation; how to appraise a mine. M. & S. P., July 28, 1917.		
DISCUSSION		
SAMPLING LARGE LOW-GRADE OREBODIES.		
By Albert Burch .....		115
Agrees with Mr. Webber that pocket mines exist which it is needless to sample; valuation on basis of past production erroneous; mill-sampling ordinarily most advantageous, but should be checked by mill-tests. M. & S. P., July 28, 1917.		
CALIFORNIA FIELD ARTILLERY .....		116
Announcement of a new branch of the service for speedy training of officers. M. & S. P., July 28, 1917.		
ARTICLES		
RELIEF FROM ANNUAL ASSESSMENT WORK.....		116
OUTLOOK FOR IRON AND STEEL ON THE PACIFIC COAST.		
By Ernest A. Hersam .....		117
Steps to promote a Pacific Coast steel industry desirable; no supply of cheap pig-iron available in the West; iron-ore deposits in California; fuel resources; oil, gas, and coke compared; methods for making pig-iron without coke should be thoroughly studied; manufacture of ferro-compounds; high prices offer opportunity to establish a Western steel industry. M. & S. P., July 28, 1917.		
Summary of leading features in a report of work accomplished, issued by the Council. M. & S. P., July 28, 1917.		
NEED OF CHEMICAL RESEARCH .....		124
Importance of research-work in pure science; without science to apply there can be no applied science. M. & S. P., July 28, 1917.		
MILL-TESTS V. HAND-SAMPLING IN VALUING MINES.		
By Morton Webber .....		125
Two methods open to the mine-sampler, hand-sampling or mill-tests; type of orebody will determine course to pursue; mill-tests should be limited to ascertaining the sampling-error. M. & S. P., July 28, 1917.		
FLOTATION—THE BUTTE & SUPERIOR CASE—I.		
By W. A. Scott .....		130
Part of argument for the defendant; shifting of ground by Minerals Separation. M. & S. P., July 28, 1917.		
RAPID SHAFT-SINKING .....		132
Gadsden shaft, Warren, Arizona, 3-compartment, sunk at rate of 9 ft. daily. M. & S. P., July 28, 1917.

Transporting Union Drill over 40 Mile Trail

## These Field Pictures Tell The Story

**The Union Prospecting Drill** is incomparably light and can be transported, handled and operated with an ease heretofore unknown for a drill having its capacity.

The Type B Drill shown in the bottom illustration weighs 2150 lb. Drills of this type are drilling 60 ft. ground and deeper, at the rate of 20 to 25 ft. a day, using 5-in. casing, which cuts a 6 $\frac{3}{8}$  in. diameter hole. The engine burns  $\frac{1}{10}$  of a gal. of gasoline per hour.

Every Drill guaranteed.

# EDITORIAL

T. A. RICKARD, Editor

SUBMARINE "is the last argument of kings," said the Crown Prince. We believe that to be true, but we do not place the emphasis on 'kings.'

MARK SULLIVAN, in *Collier's*, speaks of "Thou shalt not make money out of the War" as "an ethical hallelujah." Most men would rather make their money and then have the privilege of giving it to patriotic purpose; but when they have made it, some of them are content with the 'hallelujah.'

ALTHOUGH the embargo on exports may prove annoying not only to neutrals but to our own people, it must be noted that the value of exports of the more important commodities to Denmark, Norway, Sweden, Holland, and Switzerland increased from \$66,053,595 in 1913 to \$177,144,085 in 1916, whereas other exports, not required by the Enemy, decreased slightly, from \$201,000,000 to \$192,000,000. These figures will take a lot of explaining by neutral governments.

FROM the acting Chief Inspector of Mines at Cairo we have received a letter objecting to the statement made by Mr. Ernest H. S. Sampson in our issue of March 3, saying that the Egyptian government "has wisely made laws that preclude any possibility of individual enterprise." We are informed by the Chief Inspector that "this statement is incorrect and liable to create misapprehension," so he sends us a copy of the 'Rules and Regulations as to Mining,' published by the Department of Mines of the Ministry of Finance, Egypt, for the year 1916. The text of these regulations shows a willingness on the part of the Government to facilitate individual mining enterprise in Egypt.

CHAIRMEN of English mining companies sometimes make technical statements such as are authoritative only when backed by the name of a responsible engineer. Unfortunately, shareholders are apt to swallow assertions of a technical character when made by untechnical gentlemen prominent in finance. Thus Sir Lionel Phillips, at the Central Mining meeting, made sundry positive assertions concerning deep developments on the Rand, rich zones being said to succeed poor zones in depth. Now, if in giving such information he had quoted Mr. H. F. Marriott or some other reputable engineer in the employ of the Central Mining Corporation, we would be inclined to consider the information as having scientific value. Under the circumstances, we do not; for we remember that Sir Lionel said, in March 1910, at the East Rand Proprietary meeting, that "there seemed to be no evidence whatever that the gold contents at the

deepest levels are not fully as high as they were at the surface, or within 300 ft. of the actual surface." At that time he had the evidence of Mr. Frederick Hellman, the manager of the East Rand Proprietary, to the very contrary. We read in a recent copy of the *Financial Times* that the present chairman of this same company, Mr. E. A. Wallers, at the last annual meeting had to announce that owing to "the extremely poor development experienced during recent years", it was impossible to supply the mills with adequate ore, and that there was "no prospect of dividends for some time to come."

IN the evening paper that published the details of the draft for an American army, we were given part of the text of the new German Chancellor's speech before the Reichstag, in which he sneered at our military effort. A lack of the sense of humor is the mark of "the beast with the brains of an engineer," as Upton Sinclair phrased it; otherwise the recollection of the former Chancellor's unfortunate reference to another "contemptible little army" might have prevented Dr. Michaelis from repeating a stupidity. His predecessor has gone into the discard with his "scrap of paper" and it is now the task of General Pershing and his brave men to make the present exponent of Prussianism feel the force of another organized democracy. Our Allies have 'done their bit,' our men will 'do their durndest.'

WE publish a letter from Mr. W. G. Devereux, an engineer known to our readers as the manager of the Melones Mining Company, in which he makes a bid for volunteers to serve in the regiment of Field Artillery now being raised as a Californian unit in the army going to Europe. This is to be a Western regiment of Western men fighting under the sign of the Bear. We commend the service to our young mining engineers and miners. The artillery is a technical branch of the military organization and one for which the members of our profession are particularly fitted. We hope that they will become keenly interested in the opportunity offered to them and that they will get some of the younger men in their employ to enlist in the same regiment. Everybody cannot obtain a commission, but those that are capable and keen can feel assured of promotion in due course. In the fighting of today the intelligent and skilful soldier is not overlooked, as we know from the rapid promotion that has come to our mining-engineer friends already in the field. Rally to the Californian Field Artillery!

ACCORDING to press reports, the Secretary of the Navy has offered to purchase 60,000,000 pounds of copper at 18½ cents per pound with an adjustment later

by the Federal Trade Commission for the difference between this price and the 25 cents quoted by the producers of the metal. The latter are said to claim that they should receive not less than 25 cents per pound, in view of the rising cost of labor. Moreover, the Government has agreed to pay 8 cents for lead in contrast with the average of 4.59 per pound for the last 15 years. A price of 18½ cents for copper would, it is said, entail further labor controversies, because wages would have to be reduced in accordance with the sliding scale, but this is an ingenuous argument, seeing that 60,000,000 pounds represents only about 3% of the annual production or about one-third of the monthly production of copper in this country at this time, disregarding the temporary effect of current labor disturbances. The President has said that such prices should be fixed by the Government as "will sustain the industries concerned in a high state of efficiency, provide a living for those who conduct them, enable them to pay good wages, and make possible expansion of their enterprises," all of which depends upon the definition of 'efficiency,' 'living,' 'good' wages, and 'expansion.' It seems to us that this can be effected better by allowing the market to take its course and then imposing a heavy tax on excess profits. The lowering of price may not be much more artificial than the process by which the quotation for copper has been raised so high, and kept so high, during the last three years, but in the effort to treat everybody equitably it must be conceded that a drastic lowering of price will fall unequally on the various producers. One produces copper for 10 cents and another for 20 cents per pound, so that a lowering of 5 cents in the price from 30 cents reduces the profit of the first by 25% and of the other by 50%; and if the intention be to promote intensive exploitation of our copper resources it is best to give everybody a nearly equal inducement to go ahead. By the way, we are beginning to get new estimates of the cost of production. The *Boston News Bureau*, for example, says that "the average cost of producing American copper is not far from 15 cents per pound," whereas not long ago this same paper published plentiful statistics to show how the principal copper-mining companies were winning copper for 6 to 8 cents, and even as low as 4 cents per pound. Most of these low figures were fictitious, because they represented the bare operating cost, disregarding much of the 'overhead' expenditure, most of the development and equipment, and ignoring amortization of capital. Our Boston contemporary remarks piously: "Unfortunately many producers have not heretofore made due allowance on their cost-sheets for construction and development expenditures and depreciation, to say nothing of any allowance for depletion of mineral assets," and yet the *Boston News Bureau* has published such essentially fictitious statements with infinite gusto. "When the Devil was sick a monk he would be." In these days of stress we shall learn real economics, just as in England the mining financier has succeeded at last in persuading the tax-collector to understand that a mine is a wasting asset and that a dividend is not necessarily income.

## Steel on the Pacific Coast

One year ago pig-iron was selling at \$18 per ton. The steel-makers were excited when the price touched \$20 in February. The market has grown so used to the excuse of the War for boosting prices that it no longer thrills when the current price of pig-iron is over \$50. These fancy prices, which are not in any respect an expression of cost plus a reasonable profit, now turn to the advantage of the Pacific Coast and may effect a permanent change in the industrial relationships between the two sides of the continent. It might have been otherwise had the Government committed itself frankly and fairly to price regulation. That is one aspect of the situation. From the standpoint of the man in the street it was hoped that a plain, sensible, democratic principle would be applied, but he is now disillusioned. Certain commodities only are to be regulated, and we are not sure that, under the law, these can be controlled effectively. For awhile Congressional committees dallied with amendments that included the iron and steel industry, and then, when the Administration undertook to hurry Congress in order to get some kind of a food bill, the steel incumbence to legislative speed was thrown to one side, in consequence of which, whether the legislation be democratic or not, a new chapter in the industrial history of the Pacific Coast may be written. At \$50 per ton for pig-iron, and on the assumption that the War will last for two years, it would seem possible for blast-furnaces established in California or in the State of Washington to produce sufficient steel in one year of active operation to gain a profit that would amortize at least the larger part of the capital required. Even though only 5% of the total steel output of the country is consumed on this Coast, this proportion represents a big quantity. Just what the cost of producing pig-iron would be is difficult to say, but it is evident that there is an opportunity to establish enterprises of this character on this Coast that would survive the War. One corporation has already broken ground for an iron furnace on the Carson river, in Nevada. This is the Merrimac Steel & Smelting Company. The coke will come from Utah and the iron ore will be derived from magnetite mines in the vicinity. Deposits of hematite also exist near-by, and these could be utilized if necessary. This plant will be in operation within about nine months. A still larger enterprise is contemplated by one of the strongest capitalistic groups in California, including Messrs. W. H. Crocker, S. F. B. Morse, and B. L. Thane. It is hinted that Mr. D. C. Jackling and his friends also are interested in the venture. For two years these gentlemen have been making a survey extending from San Diego to Alaska. They have examined every iron deposit along the Coast, and have made elaborate investigations into the available source of iron ore and have completed arrangements for making by-product coke. The smelting-plant will be established at Lake Washington on the outskirts of Seattle. The plans of the company have not been made public, and, in fact, we understand that the financing of

the operation has not yet been perfected. This seems, however, to be a mere detail, for it is certain that ground will soon be broken for a plant if arrangements can be made to insure delivery of the necessary equipment within such a period of time as will enable them to take advantage of the prevailing high prices. It is this great margin that offers the opportunity for establishing an enterprise that may endure.

The increase in the manufacture of steel on the West Coast has become important. Four years ago there was not a single steel-plant fronting the Pacific Ocean. Today 16 open-hearth furnaces are in operation, mainly on scrap, which is selling at the rate of \$29 for cast-iron and \$42 for steel. The Noble Electric Steel Company, which began many years ago to experiment on the manufacture of steel with the Heroult type of furnace, has passed through a costly experimental stage to one of profitable production as a manufacturer of ferro-silicon and ferro-manganese. A special type of furnace has been developed known as the Frickey, possessing features said to introduce greater economy than was possible by the original Heroult process. Each of these is equipped with four graphite electrodes manufactured at Niagara Falls. In the production of ferro-silicon they use a local supply of exceptionally pure silica and a remarkably high-grade magnetite, which, as charged into the furnace, assays 70% metallic iron. The same company is erecting three single-phase furnaces, each of 2½ tons capacity, for the manufacture of ferro-chrome. The two larger furnaces making ferro-silicon and ferro-manganese have a capacity of eight tons each per diem. All of these products are being sold to steel-makers on the Pacific Coast that ventured to engage in the industry under the stimulus of War prices. In view of the fact that the expected benefit from the Panama Canal in low freight-rates for our domestic inter-oceanic commerce is not to be realized, the new iron and steel industry developing on the West Coast will always enjoy the protective differential corresponding to the trans-continental freight-rate on pig-iron. An academic discussion of the iron and steel problem on the Pacific Coast by Mr. Ernest A. Hersam is printed elsewhere in this issue. It will be read with interest because it reveals the difficulties under which the development of such an enterprise has hitherto labored. Professor Hersam is justified in saying that the special process for producing iron without the use of blast-furnaces and high-grade coke deserve to be carefully investigated with reference to Western needs, and it would seem, furthermore, that the great abundance of electric power cheaply available in the mountains of the West presents an opportunity for a greater development of the electric iron and steel industry than is possible anywhere else in the world, with the exception of Norway. About 44% of the total available water-power in the United States lies west of the Sierra Nevada, nevertheless, it is interesting to see that the starting of the iron industry on the Pacific Coast will be along old lines, sustained by a favoring margin of profit made possible because of inflated prices due to the War.

## Sampling Large Low-Grade Orebodies

The editorial article published in our issue of May 26 on this subject has elicited the discussion desired. Mr. W. J. Loring lays emphasis on the fact that it is not the number or weight of the samples, but their representativeness that counts in the appraisal of a mine. The two examples he quotes, and the description of the method by which the work was done, should prove helpful to our young engineers, for Mr. Loring has 'made good' on the samplings he describes by developing profitable enterprises on both of them. The collection of evidence is only half the task: the deduction from that evidence is at least as important. The first must be accurate in order that the second may be correct; but it is easier to make a careful sampling than a true diagnosis; therefore the personal equation continues to be the basic factor in mine-appraisal. Next we have the letter from Mr. Morton Webber, who also contributes a thoughtful article to this issue. We are grateful to an engineer so busily engaged for finding time to enrich our pages so effectively. In his letter, which followed Mr. Loring's, he returns to his former friendly controversy with Mr. L. A. Parsons, whose article we re-published in our issue of May 26. Mr. Webber insists that there are mines that cannot be sampled; in such mines the distribution of rich ore is so sporadic and irregular that no rigid system of sampling is of use as a means of obtaining reliable data for valuation. The argument is that if a large cake contains a dozen raisins distributed at random, no two, nor even four, cross-sectionings of the cake by a knife would furnish a basis for estimating the number of raisins in that cake. The only way to find out would be to eat the whole cake. Skill in sampling, therefore, is wasted on a 'pockety' mine. Mr. Albert Burch, who writes in this issue, agrees with Mr. Webber, instancing the Tightner as a case in point. He also describes a similar mine in Oregon. A wise man knows the limitations of his technique. To Mr. Richard A. Parker we are indebted for the suggestion that sub-sampling is necessary for discriminating inferences; he states a truth known to experienced practitioners, like himself, that any pronounced departure from the normal average of an orebody should be investigated by re-sampling the abnormal length of lode, taking fresh samples at short intervals, in order to ascertain the importance that should be given to the abnormality. Mr. Parsons contributes a valuable article, in the writing of which, he informs us, he consulted Mr. William W. Mein. These engineers are vigorous exponents of the maul and hammer, although recognizing the proper function of the mill-test. Samples must be representative and accurate, he says rightly. The mill-test may be representative, but it represents only one or two parts of the mine; it is likely to be "broadly selective." That is a true word and right worthy of acceptance. On the other hand, the mill-test is more accurate because the bulk of it is so large as to minimize the aberrancy caused by particles of gold. Such free gold vitiates the accuracy of a 50-pound sample much

more than that of a 100-ton mill-test. In the one it may be abnormal; in the other it and others like it are normal. The accuracy of the moil-sample is dependent upon the human factor; mind no less than muscle is required for taking a true sample. On the other hand, the breaking of many moil-samples distributed at uniform intervals over the length and breadth of the orebodies gives an opportunity for collecting much collateral information concerning the geological structure and other peculiarities sure to exert an important influence upon the subsequent exploitation of the mine. All these points are brought out by Mr. Parsons most lucidly. Next, our friend Mr. T. H. Leggett lays stress on the word 'representative,' and thereupon suggests that mill-tests may lack this quality because the ore mined for milling usually does not come from a sufficient number of places, or, rather, that not a sufficient number of mill-tests of ore from various parts of the mine are made. That is why moil-sampling is usually more reliable. To make mill-tests so numerous as to be representative may entail a costly scheme of development. The engineer has to cut the garment according to his cloth; for time and money are two basic factors in engineering. Mr. Leggett says, a mine that cannot be sampled is a good one—for the owner—to keep. With this opinion we are inclined to agree. It is unwise to buy a pig in a poke. The unsamplable mine is rarely appraisable; the element of risk is so large; the venture is so much of a gamble, that such mines are best left to men that have plenty of capital and their own experience to guide them. If Messrs. A. DeW. Foote and William Hague made money out of the Tightner mine, for example, it was because they were living in the district and knew not only the past history of the mine, but the idiosyncracies of the deposits in that locality. Mr. Burch endorses Mr. Leggett in the emphasis upon 'representative' and closes his own contribution with the sensible advice that where reliable data are available a preliminary moil-sampling may be set aside in favor of mill-testing, although it is clear from the context that he does not expect the data furnished by the vendor to be often so reliable as to warrant abstention from the moil-sampling. He refers to the 'cleaning-up' of the mill as a source of error. Of course, it is; and one that always predisposed the present writer against mill-tests on a small scale.

The foregoing summary of the high lights in the preceding discussion of a most practical subject will serve to increase interest in the article by Mr. Morton Webber on the respective merits of moil-sampling and mill-tests. He has gone to some pains to make clear his argument by citing three examples taken out of his own recent experience. He lays stress on the fact that the terms of an option necessarily influence the choice of method; the mine-valuer must have business acumen as well as technical skill if he is to prove a safe adviser to the buyer of mines. The choice between the moil and the mill is conditioned upon the circumstances of each option and of the mine optioned. In making a representative shipment of ore, it is necessary that each stope shall contribute its

representative weight, says Mr. Webber. That is a point well taken; so also is the suggestion that the comparison of the moil-sampling with the mill-test of a stope gives a sampling-factor, or ratio of sample-assay to mill-bullion, that is most valuable. He lays stress on a detail usually overlooked, namely, the uniform mixing of samples after they have been crushed, by allotting a definite period for the operation. He believes that a mill-test is useful for ascertaining the metallurgical character of the ore and for establishing the sampling-error, and in his third example he shows that moil-sampling of ore already exposed may not furnish the information most requisite for estimating the future prospects of a mine. His article is one of the most useful we have had the pleasure of publishing; it is a clear gain to the technology of the subject. It remains to state once more that sampling of any kind must be made to yield results indicative of future mining operations, those operations anticipated by the purchaser of the mine. Sampling misleads because it is done on a laboratory scale and style, as it were. That is why sometimes a mill-test furnishes a check, because in blasting ore for a mill it is broken in a manner more nearly like ordinary stoping. As Mr. Parsons suggests, the moil-sampling of a narrow width of ore is likely to disregard the stoping-width. The moil breaks the ore more cleanly than the dynamite in a drill-hole; the sample is free from the casing, wall-rock, and other diluents that create discrepancies between the report on a mine and its subsequent life-history. What we need today is a sufficient collection of post-mortems, say, two or three hundred reports by capable engineers supplemented by the later records of the mines themselves, to furnish us with the factors of error, and the reasons for them. One factor is incontestable, and that is the lowering of the grade. Most reports on most mines give a grade of ore lower than is subsequently mined. This is due not only to the cleaner breaking of ore by the samplers, but to the advancement of metallurgy, the betterment of ore-breaking, and other improvements that enable the mine-manager to reduce the grade below that of the appraising engineer's report and to prolong the life of the mine economically, that is, within limits that recognize the value of money and the need for amortizing capital. Finally, we suggest to the profession that there is an inherent discrepancy between the sampling of a mine and the actual exploitation of it. The sampler's ideal is to obtain a true average, to be non-selective, whereas the miner, the manager of a mine, inevitably selects, he extracts ore that will yield the profit on which the enterprise is predicated. That is why the sampling of a mine under option so rarely corroborates the estimate based on past production. To be a good appraiser therefore the engineer must be a man of constructive imagination, a man with foresight, able to foresee how the mine is going to be worked. He must be able, in a measure, not only to write last year's almanac but also to predict the future; and to do that he must have been, at some time, a mine-manager himself.

We shall be glad to publish further discussion.

# DISCUSSION

*Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.*

## Sampling Large Low-Grade Orebodies

The Editor:

Sir—I have read with considerable interest the discussion of this subject, as printed in recent issues of your paper, which, I understand, had for its inception articles from the pens of Messrs. Morton Webber and L. A. Parsons.

Mr. Webber took the ground in the beginning that there are mines (his class 5) the sampling of which is useless and on this point Mr. Parsons takes issue, but I decidedly agree with Mr. Webber, though I also think that, fortunately, mines of class 5 are rare and therefore relatively unimportant. They are "freak" mines, but they do exist and, in a later letter, Mr. Webber cites the well-known case of the Tightner as an example. From my own experience I might mention one that is even more extreme than the Tightner, being a mine in eastern Oregon which I visited several years ago.

At the time of my visit, the un-stopped portion of the vein was well blocked out by drifts, cross-cuts, and raises, which could have readily been sampled, but the mine had been well managed and an examination of the well-kept records of production extending over a period of several years showed that sampling would have been entirely useless. These records showed that the average ore had about paid expenses, and that the dividends paid coincided almost exactly with the combined values of two pockets of extremely high-grade ore totaling less than two tons in weight. I understand that a few other mines of a similar character have been found in the same district, but this is the only one of which I have personal knowledge. Such examples would seem to me to establish the existence of mines belonging to Mr. Webber's class 5, and nothing that has been said by his critics, including Mr. Parsons, has convinced me that it is not useless to sample them. The discussion, commenced in this way, has been broadened by your editorial of May 26 and applied to mines of a different and more important class, namely, those containing large bodies of rock which, taken as a whole, constitute payable ore, but within which the gold is so unevenly distributed as to render them difficult but not impossible of sampling, and the question has narrowed to one of mill *versus* mill-test sampling. On this question, I believe, Mr. Leggett has hit the nail squarely on the head by the use of the word "representative"; for if the mill-tests can be made on rock as truly representative of the average ore as the mill-samples, then it would seem that the mill-test method should be more accurate than that by

mill-samples, because of the elimination of many of the minor inaccuracies incident to such sampling. The three most frequent causes of error by this method are probably (1) tendency of operator to cut a disproportionate amount of either hard or soft rock, (2) liability to mixture of sample with particles of dust and pieces of rock falling from points outside the sample cut, and (3) danger of salting from a single small piece of gold which finds its way into the very small proportion of the original sample that finally goes to the assayer's crucible.

Admitting then, for the sake of argument, that the mill-test can be made the more accurate of the two methods, if it is quite as representative, how can it be made representative? First, the openings to be sampled must be in such positions within the vein as to develop ore of the same average grade as that of the entire orebody, and this applies quite as much to openings which are to be sampled by hammer and moil as to those from which mill-tests are to be made; and in the failure to so make the preliminary openings upon the vein, I believe we find the source of future disappointments more often than in inaccurate sampling. Given properly placed openings the next step in sampling by mill-test should be to cut a sample of uniform width, but this must also be done in moil-sampling, and except in cases of soft or caving ground is quite as easy in the one case as the other. It is true that the length of a cut for a mill-test must be made several times as great as that of a single moil sample in order to avoid frequent cleaning up of the mill, which is itself a source of error, but, as the object is to determine the average value of a large orebody which previous development has shown to be probably valuable and *not* to pick out pay-streaks, for selective mining, there could be no objection to including within a single mill-run all of the samples from an entire cross-cut, or a long section of a drift.

As to the valuation of a mine upon the basis of past production, there can be no doubt that such a method is erroneous unless the past production has come from workings uniformly distributed through sections of the orebody to be mined in the future. Otherwise such past production is representative of nothing except the part of the mine already exhausted, and as you have very well pointed out, a good miner is quite likely to select the best part of his mine for his first stoping. I have frequently said that one could pick out the best part of any orebody by examining a longitudinal section of the workings and noting what portions had been carried in advance of the remainder.

Regarding the questions of cost and of time consumed,

there would seem to be no doubt that ordinarily the advantage lies with mail-sampling, though this advantage in the matter of cost need not be so very great, if, as is usually the case under mining options, the purchaser has the right to retain all of the mineral recovered, less a small royalty. Furthermore, it costs a great deal of money to build an operating plant for a large low-grade mine, and no one financially able to build such a plant should neglect to forestall the chance of losing his entire investment by failing to use the best means available for determining in advance the value of his mine, even though the best method should be more expensive than the next best.

In conclusion, I would advocate for a large low-grade mine at which no reliable data of the results of development are available, a preliminary mail-sampling followed by mill-test sampling, but, where such data are available, I believe one might safely dispense with the mail-sampling and depend solely upon mill-tests for determining the value of the property.

San Francisco, July 18.

ALBERT BURCH.

### California Field Artillery

The Editor:

Sir—It may be interesting to those of your readers who contemplate military service, but have not as yet determined in what arm or branch they prefer to serve, to know that a Field Artillery unit of four batteries has been authorized to be raised through the National Guard of California which will, in effect, be a volunteer organization. The recruiting of this organization has been given to the San Francisco Cavalry Troop, which is an officers' training organization that has been commanded and trained by a regular army officer for the past two years and which will be used to form the nucleus of the commissioned personnel.

The movement has the hearty endorsement of such eminent officers as Major-General John J. Pershing, and Major-General Hunter Liggett, Commander of the Western Department.

The commander of the new organization will be an expert artillery officer from the Regular Army. Some of the commissioned positions are open to be filled from the enlistments, as well as most of the non-commissioned personnel.

The Field Artillery is the branch of the service that pre-eminently appeals to the mining profession and to the technical man, and in the present war has rapidly grown to be the most important arm.

The most desirable qualifications, second to actual military experience, are a knowledge of horses, and the mental and manual training obtained from having handled machinery, but any able-bodied man is acceptable. It is expected that this organization will see active service just as soon as its training reaches the required degree of perfection, and it is hoped that the quality of the men who will join will reduce this period to a minimum.

Full information can be obtained at the Recruiting Headquarters, 210 Montgomery St., where enlistments

are rapidly coming in. We have assurance that as fast as batteries are recruited to the necessary strength, they will be recognized and the men who have enrolled will be exempt from the draft.

CALIFORNIA FIELD ARTILLERY.

By WILLIAM G. DEVEREUX,  
Vice-Chairman Recruiting Committee.

### Relief From Annual Assessment Work

[The following resolution exempting enlisted men from the obligation to perform annual labor on mining locations has passed both houses of Congress, and is merely awaiting the signature of the President to become law. For the benefit of those whom it may affect we reproduce it verbatim.—EDITOR.]

#### JOINT RESOLUTION

To relieve the owners of mining claims who have been mustered into the military or naval service of the United States as officers or enlisted men from performing assessment work during the term of such service.

*Resolved by the Senate and House of Representatives of the United States of America in Congress assembled,* That the provisions of section twenty-three hundred and twenty-four of the Revised Statutes of the United States, which require that on each mining claim located after the tenth day of May, eighteen hundred and seventy-two, and until patent has been issued therefor, not less than \$100 worth of labor shall be performed or improvements made during each year, shall not apply to claims or parts of claims owned by officers or enlisted men who have been mustered into the military or naval service of the United States, so that no mining claim or any part thereof owned by such person which has been regularly located and recorded shall be subject to forfeiture for nonperformance of the annual assessments until six months after such owner is mustered out of the service or until six months after his death in the service: *Provided,* That the claimant of any mining location, in order to obtain the benefits of this resolution, shall file, or cause to be filed, in the office where the location notice or certificate is recorded, within ninety days from and after the passage and approval of this resolution, a notice of his muster into the service of the United States and of his desire to hold said mining location under this resolution.

MANGANESE oxides in large quantities are characteristic of a number of the silver deposits at Philipsburg, Montana, notably in the Cliff and Trout mines. The mineral occurs as pyrolusite derived from the alteration of rhodochrosite, which is abundant in the gangue of the Philipsburg ores. The accumulations of pyrolusite in these deposits have again attracted attention owing to the high price of manganese, and the shipments of this ore from the district now amount to approximately 500 tons weekly.

# Outlook for Iron and Steel on the Pacific Coast

By ERNEST A. HERSAM

Whether or not the Pacific Coast states can profitably produce iron and steel from the ore, or can develop later an extensive iron industry, is a question that demands an answer. If the industry is practicable, steps to promote it are important and should be encouraged. If there are qualifications or limitations to iron smelting in the West, the people ought to know of it. To consider the possibility of developing an extensive iron and steel industry through the actual smelting of iron ore, leads to some fundamental scientific and economic considerations. It is an easy matter to define the requirements of iron manufacture as represented in present practice, and to observe whether or not these can conform to given local conditions in future practice. It appears at once to be extraordinary that the iron ores of the West Coast have not contributed more abundantly toward the iron-output of the United States, yet the Pacific-Coast States are importing from the East and from abroad practically all of the iron used by them in local construction and manufacture. This backwardness is seen to limit the local expansion of manufacturing industry, dependent as it is upon pig-iron and the iron and steel products derived from pig-iron.

In the ordinary process of iron and steel manufacture the mills and foundries designed to supply the metal in the forms required in commerce are based upon supplies of pig-iron that are easily accessible in ample quantity. Without such an abundant supply of pig-iron, no well-developed and extensive manufacturing industry can exist. Foundries and rolling-mills that rely on distant sources, produce only with difficulty and at high cost, and the manufacture of small articles, machinery, and varied appliances, in which iron and steel are essential, is monopolized by districts favorably situated.

As a fundamental commodity pig-iron ranks with timber, food, and fuel; and these elements of the commercial world are the determinants of industrial growth, as are air, water, and sunlight of human life. An available supply of iron indicates that a region will become densely populated, that the harbors will be crowded with shipping and that great cities will be built. The industries on the western coast of the United States, that started from resources other than iron, and have grown despite the absence of a local iron-supply, have remained at the limit set by the local cost of iron and steel.

There are some who hope for an abundant supply of Californian pig-iron in the near future, at a price not higher than that prevailing in the iron regions of the East. Others believe that the Pacific Coast does not possess the essentials for a self-supporting iron-industry, and that no relief from the high prices would result even if

local production were attempted. A potential supply of iron does not consist solely in the presence of the ore, but requires also a fuel such as can be used to smelt it. The economic tendency of the iron-industry, the world over, is toward centralization, and is opposed by the extension of iron-production to the West. Though there are ores, and oil, and electric power, and markets on the Pacific Coast, similarly there are hundreds of millions of tons of unmined ore available in the densely peopled states of the East, but remaining unused because of cheaper ore 1000 miles distant.

The ore resources of the Pacific Coast appear to warrant the development of an iron-smelting industry. The hematite deposits of Eagle mountain, in southern California, have been shown to be ample for operating a blast-furnace for 200 years. Some of this ore is pronounced to be of the finest quality. Much is judged to be capable of being enriched by sorting. Shasta county, in California, is also capable of supplying iron ore for an important industry. In Madera county, California, there is a body of ore estimated at 50 to 100 million tons of good quality. Elsewhere, as in San Bernardino county, in the Kingston mountains, and also in Oregon and Washington, there is ore said to be suitable in quality and amount for smelting operations. While the deposits of iron ore on the western coast are small compared with the great reserves in the East and in the Lake Superior region, they are adequate, so far as the ore is concerned, to meet the local demand, and are worthy of attention. In recent years the extensive deposits of black-sand, which abounds on the Pacific Coast and elsewhere, has been looked to as an attractive source of iron. These sands are known to contain, amongst other minerals, a small proportion of magnetite. While there is little possibility of using widely scattered material of this character for extensive iron-manufacture, yet the improvements in separation and the demand for the contained minerals, other than the magnetite, suggest using the material for iron or steel-manufacture in a small way. The backwardness of the iron-industry in the West is the direct outcome of the economy of production in the East; and it is the relative cheapness of the Eastern supply that renders the western condition tolerable. Moreover the demand for iron and steel in the West covers a wide variety of forms; and plants to supply the Western needs are called upon to furnish shapes difficult to produce at any single establishment. The local consumers would be limited if made dependent upon a local supply. A single blast-furnace would fail to supply the varied demand for local consumption. The limitation, however, that is most serious to production in the West is the absence of fuel of the

kind commonly required in iron smelting. To obviate the cost of transportation of coke there arise the problems of novel metallurgical methods utilizing the heat-energy that locally can be had.

The sources of coke available in the West are those from China or abroad, the development of the coking coals of Alaska, the coke of Utah and Colorado, and finally there arises the question of adaptation of practice to permit of employing coke that can be made from the coals of Washington. There remains the possible substitution of other fuels for the needed coke. The production of a satisfactory coke has been claimed to be possible as a by-product from petroleum, when treated by a special process in gas manufacture, with this end in view. Commercial demonstration of the possibility of doing this, however, is as yet wanting. The use of natural oil, with regenerative appliances, is possible, but only under important limitations and with diminished heat-efficiency. California, which is one of the most productive oil fields of the world, would be in a position to profit by the use of its natural resources in this way. The use of electric energy in iron-smelting has been demonstrated as not only possible, but practicable, under certain limitations. In this particular the West, possessing available water-power in the Sierra Nevada and the Cascade ranges, offers a cost comparing favorably with such power elsewhere, and is in a position to profit by this extension of the industry.

The treatment of iron ores, by the standard processes, is an industry involving large tonnages and broad markets, while the mining, transportation, and smelting are circumscribed by the low value for a given weight. The average value of iron ore, such as is now derived from the Lake Superior region, or from Cuba, Spain, Canada, and elsewhere, is normally about \$3 per ton at seaboard, or at the smelting-centers. The cost of the ore at the mine may be rated at 50c. to \$1 per ton. The cost of ore, at \$3, at the Eastern smelting-centers consists, therefore, largely in the cost of transportation, which commonly amounts to two or three times the cost of mining. The handling and transportation of large tonnages of iron ore of this relatively low value calls for accessibility, either through natural ways of transportation or the actual proximity of the ore to regions where the metal is consumed. The average value of coke at tidewater, for example, at Baltimore, may be taken as normally about \$2.50 per ton. Coke in the State of Washington costs twice this amount. Nearly two tons of ore and one ton of coke are required to produce one ton of pig-iron. This ton of pig-iron, of average grade, and at normal times, is worth approximately \$15. The price at present is three times this sum. In terms of normal operation, over a long period, three tons of ore and fuel, having a value of \$8 or more, are required to produce one ton of pig-iron valued at \$15. When such prices and production are contemplated for the West, the cost of transportation eclipses all other items. The increment in the ton-value of the material affected by the transportation and smelting, based upon the combined weight of fuel and ore, is

less than \$2 per ton. A slight increase in the cost of transportation easily consumes any allowance for the cost and profit in smelting. Water-transportation in the movement of iron-ore has been rated at 0.09c. per ton-mile, and land-transportation at 0.66c. on well developed lines. At this rate, the entire increment of operation would be consumed by a land-haul of the coke of 1000 to 1100 miles, or of the ore for 500 miles or more, or of the ore and coke for about 333 miles. In water-transportation, the distance would be seven or more times as great at a corresponding cost.

The freight-cost on pig-iron, at 60 to 75c. per hundred, from Pittsburgh or New York, or 55c. from Chicago, brings war prices to the western coast in times of peace. Iron produced locally can be marketed, normally, at nearly \$30 per ton. At any time, however, local smelting brought into competition only with existing prices, with the freight-costs added, brings no relief to local industries as a whole. The cost of production in the West must more nearly approach that in the East to warrant interest in the turning of industry from its established channels.

The extension to the West Coast of the standard industry of iron-smelting with coke is seen to require, not so much a gradual growth of many industrial interests as a single independent and energetic interest. By the standard methods of treatment, we could consider the iron industry to comprise five dependent steps. The ore is reduced to metal and manufactured into rails, rods, bars, plates, sheets, and structural shapes, or cast into forms for the consumer. The first, and primary operation, that of smelting the ore in the blast-furnace, is the only missing element to a complete chain of independent production in the West. This operation, carried on extensively in the Central, Eastern, and South-eastern parts of the United States, and in the West as far as Colorado, supplies pig-iron for the iron-foundry and the steel-plant, which may be regarded the second and the third branches of the industry. No large-scale substitute for the production of pig-iron in the blast-furnace has been demonstrated, as yet, to be practicable. The iron foundries are commensurate with the local need. By these the waste cast-iron, gathered from the surrounding country, is brought again to useful application. In the West, many foundries are relatively small, and are operating at a profit. Coke is the fuel commonly employed, but while a superior quality is to be preferred, grades inferior in some regards can be used. Oil fuel has been used in the foundry-cupola with the promise of economy and success. In experiments at one of the foundries in San Francisco, it was stated that about 8 gallons of crude oil per ton of iron would serve the cupola. The steel-plants on the Pacific Coast are relatively small, but for some years have been growing in importance. Plants of the open-hearth and bessemer types are represented. In the open-hearth plant, as operated in the East, pig-iron furnishes the greater part of the metal for the steel product, but with the pig-iron is used a suitable proportion of pure iron ore and also steel and iron scrap. So far as

ELECTRIC FURNACES AT HEROULT, CALIFORNIA, PRODUCING FERRO-SILICON

NOBLE ELECTRIC STEEL PLANT, HEROULT, CALIFORNIA

ore is used, this furnishes metal direct to the steel. The plant, to this extent, becomes a direct producer of steel from ore. The fuel commonly desired is producer-gas, but for the manufacture of gas a wide variety of fuels, including oil, can be used. The adaptation of the process to the West has led to the use of oil-fuel direct, with much success. Since, however, the tonnage of metal produced at the steel-mill practically equals that received in the raw condition, there is always the competition of steel made in proximity to the iron-furnace. The limitation falls more seriously upon the bessemer process than upon that of the open-hearth. The rolling-mills may be regarded as the fourth division of the industry. These supply the smaller shapes of structural steel to the building-trades and to the manufactories of machinery, including bolts, nails, rivets, and a great variety of iron and steel articles. These industries are acquiring importance in the West. The steel-foundries may be considered the fifth branch of the industry. There is an increasing demand for steel castings, which gives reason to believe that the time will come when light steel-castings will replace much of the heavy iron-structure in machinery. Waste steel has offered a supply of metal at a price not before equalled. The local supply of iron and steel is becoming depleted, however, by the heavy demand and high prices prevailing. The cost of producing steel from scrap in the West has been such that, in the past, in spite of the local supply of waste metal, manufacturers have found it less costly to purchase steel from the East than to produce the metal locally from the scrap-material available. The steel-foundry can operate with coal, coke, producer-gas, oil, or with electric energy. In these plants throughout the country the labor is skilled, and the demand for the products is largely local. The plant in many cases is an adjunct of a factory for making special machinery. The appliances are varied in which the melting of steel is performed. Much cast-steel is made by the crucible process. In the past few years the electric-arc re-melting furnace has come into application in many places.

There has been no success, so far, in making pig-iron on an extensive scale without coke. The use of fuel-oil, or of electric energy for the production of iron from ore, would be the first expedient in the development of a Western industry. Whether or not such methods can be developed to compete with existing practice is the problem to be considered. For the treatment of iron ore in the manufacture either of steel or iron, it is seen that the direct use of the ore along with a due proportion of the reduced metal is possible to a limited extent. Here the ore, or oxide, not only furnishes metal, but serves a useful purpose as an oxidizing agent. The oxidizing action, however, pre-supposes that there has been a previous reduction of some constituent of the charge. The direct use of iron ore in large foundry-furnaces for producing cast-iron directly from ore reverts back to the earliest days of blast-furnace smelting, and promises little in the way of practical economy. The direct reduction of iron, as in the American bloomary-process, is

primitive and impracticable under existing labor conditions. The reduction of iron sponge, in a separate operation by the use of fuel other than coke, followed by the melting and casting of this reduced metal into steel-ingots of low carbon-content, involves a double operation which, compared with the standard processes is costly, since it divides the operation which, in the blast-furnace is conducted with the fullest economy in a single operation, into two separate steps, performed at different times, and with two separate applications of heat.

In the smelting of iron there is chemical and physical work to be done, only in part by the application of heat. There is slag to be melted, water-vapor, carbon di-oxide and other gases to be expelled, and various heat-absorbing side-reactions to be satisfied. A part of the heat is wholly lost in the liquefaction of products and in the formation and expansion of escaping gas. Notwithstanding the complex distribution of the energy, there is a part that is to be regarded as peculiarly and unalterably necessary to the process. This energy performs the service of reducing the oxide to metal. The heat consumed in fusing the metal may be partly recovered upon solidification, by improvements in construction that have been suggested from time to time. So also heat that is lost by conduction and radiation may be further decreased by improved heat-insulation or by improved furnace design.

In the case of the energy that is required to reduce the iron and form the desired iron-carbon alloy, it will be seen that the interchange of the forms of energy is more difficult. In any case, the low value of the material and the high tonnage to be treated require low cost. Hydro-electric energy comes into open competition with the energy derived from petroleum or from coal. Electric power, light, and heat, however, with the improvements in modern industrial and domestic applications, has become a refined form of energy meeting an increasing general demand. Oil, similarly, as a direct source of heat, is to be expected to find an indefinitely increasing market through the extension of known devices and methods of application and facilities for transportation. The maintenance of the high temperature required in the hearth of a blast-furnace requires consideration apart from that for other appliances. A reaction is sought in the blast-furnace by which metallic iron and a carbide of iron are formed. The reaction, which occurs only at a high temperature, absorbs heat at that temperature. Such reactions are likely to require appliances that are wasteful of energy. There is loss of heat in elevating the materials to the temperature of reaction and of obtaining a return from the heat contained in the products. Here the reduction of the oxide to metal requires a temperature ranging from 800° to 1800° F. In electric smelting, it is a simple matter to produce the heat, required for the reduction, by the arrangement of the electric arc, or by other suitable electric resistance. Reduction work, however, is not obtained by the heat alone. Carbon, in some form, is required in addition to the electric energy. The electrolytic capacity of the appliance

is too small and the electrolytic action too slight to justify the maintenance of the high temperature to secure it. In the effort to use oil in iron smelting, as a source of the heat, the products of combustion become troublesome. The gas from the combustion contains moisture from the hydrogen content of the oil. The water-vapor, along with the carbon di-oxide from final combustion, produce an oxidizing effect upon the iron and carbon, and interfere with the reduction.

The energy required in iron-smelting can be expressed in simple units. The reduction of one pound of iron from the sesquioxide (hematite) requires the consump-

satisfying the heat-absorption. With solid carbon fuel, producing carbon monoxide as the end-product, there is an absorption of heat throughout, and the reaction is not self-sustaining but requires supplementary heat. The carbon necessary to effect this reduction would be approximately  $\frac{1}{3}$  of the weight of the iron, in a case where carbon escaped from the reaction in the state of the higher oxide. Where the product of the reaction is carbon monoxide, the weight of carbon involved would be twice that amount. Similarly, if this carbon had been previously oxidized to carbon monoxide, and the reduction of the iron were performed by the carbon monoxide,

NOBLE ELECTRIC STEEL PLANT: IRON MINE ON RIGHT

tion of fuel capable of yielding 3141 B.t.u. This heat, capable of yielding 3141 B.t.u., is absorbed in the process, and is not available as a heating effect. Aside from any consideration of heat required to satisfy this consumption, a given amount of carbon or carbon monoxide is necessary to carry on the action. However the reduction be performed, whether with carbon, carbon monoxide, hydrogen, or hydrocarbons, and whatever the heat-value of the fuel used to perform the reduction, this constant amount of heat-energy is absorbed from the reaction at the high temperature necessary. The heat-balance of the reaction of oxide with the fuel shows a slight excess of heat, which results in elevating the temperature after

the amount of carbon represented in the reaction would be approximately  $\frac{1}{3}$  the weight of the iron. The reduction of such ore requires the application of carbon ranging from  $\frac{1}{3}$  to  $\frac{1}{2}$  lb. per pound of iron produced; and in the use of this carbon little or no heat is produced over and above that consumed by the reduction of the iron.

The fuel consumed in blast-furnace practice approximates one pound of coke per pound of iron produced. The heat-value of coke, or of a medium grade coal, may be taken as 14400 B.t.u. per pound. This pound of coal or coke is equivalent to about 5.6 hp. hr. or 4.18 kw. It is the heat that would be expected from the complete combustion of about  $7\frac{1}{2}$  cu. ft. of natural gas,  $2\frac{1}{2}$  lb. of

dry wood,  $\frac{2}{3}$  lb. or  $\frac{1}{12}$  gal. of petroleum. Its service in reduction is to furnish 3141 B.t.u. for the conversion of the oxide into 1 lb. of the metal. The balance, or  $\frac{1}{3}$  of its heat-value, is available for the liberation of heat. For the economy of coke and the substitution of as much coke as possible by fuel other than coke, or by energy derived otherwise than by the combustion of coke, it is natural to look to some process that may permit of employing the  $\frac{1}{3}$  to  $\frac{1}{2}$  lb. of coke as the reducing agent, and of supplying the remainder from other fuel or other agents that can be locally provided. The application of heat by means of any exterior contact is attended with serious physical losses. The application of supplementary fuel within a reducing appliance, on the other hand, contaminates the gases which are desired to exert a reducing effect. The use of hydrocarbon fuel particularly, in the blast-furnace, either in the zone of fusion or of reduction, is attended by incomplete reaction and incomplete recovery of the heat-value. The employment of electric energy is opposed by a high unit-cost. The electric furnaces thus far devised, however, are small and ill-adapted to conserve the heat. In smelting iron by the use of any fuel, the full efficiency of the process can be secured only by utilizing the chemical energy contained in the waste-gas. Such waste-gas, of necessity strongly reducing, when issuing from the smelting appliance, is a fuel superior to any that easily can be supplied from an auxiliary source, produced from other fuel. The heat-units described above represent the effect of complete combustion of the gas. In modern blast-furnace smelting, the heat, latent in the waste-gas, is utilized by burning the gas where complete combustion can be secured, and employing the heat thereby developed for pre-heating the entering air, or for the generation of steam. The recovery of the waste-heat is an essential economic factor.

Efficiency under the conditions of high-temperature reactions generally implies a need of recovering the heat latent in the products issuing from the appliance after the reaction has occurred, and the avoidance of loss by radiation and conduction. In certain metallurgical operations the desired reactions occur spontaneously, and the production of heat sustains the action, when once the initial means are provided to produce the requisite temperature.

When the magnitude of the blast-furnace is considered, with its height of 75 ft. or more, and its diameter of 15 ft. and its large content, relative to its exterior exposure, and when the long experience with the blast-furnace is considered, with the improvements that time and ingenuity have wrought in its details, there will be less expectation of substituting small appliances for it with an idea of securing comparable efficiency. No one objects to the blast-furnace as an economic appliance. The objection is to the restriction in securing practical fuel. The effort to use a volatile fuel in the blast-furnace, or in any direct modification of a blast-furnace involves ineffectual reduction, and poor economy in heat units. In the shaft-furnace there is difficulty in keeping the charge open for the passage of the necessary gas.

The use of solid fuel of high fixed-carbon provides the means for this. The use of electric energy for the production of the pig-iron fails to provide the required reducing action. In addition to heat derived from this source, some  $\frac{1}{10}$  lb. of fixed-carbon is required for each pound of pig-iron reduced. The gaseous product is irregularly supplied, and its utilization has not thus far been made practicable. The consumption of electric energy is found practically to amount to 2200 kw.-hr. per ton of iron produced, in addition to the coke, charcoal, or other fixed-carbon fuel consumed. Here the substitution of electric energy for coke results in the saving of approximately 0.6 tons of coke per ton of metal, at the expense of 2200 kw.-hr. In Sweden, electric power has been used for the production of pig-iron, but the economic conditions differ from our own. At Heroult, California, with iron ore and power available, the electric furnace has given excellent service, not in the production of ordinary pig-iron, but in the manufacture of special alloys. For the manufacture of steel, either from blast-furnace products, or directly from ore, the electric furnace is coming more generally into prominence. There are in use in the United States 43 furnaces of the Heroult type, the largest of which has a capacity of 20 tons, and 14 of the Snyder pattern. The industry is growing, and the present conditions offer extraordinary encouragement for its development. The manufacture of steel, however, is an industry subordinate to the manufacture of pig-iron.

The development of a complete iron industry in the West, to include the production of pig-iron, demands special encouragement. Ideal conditions are not to be found. The abundant coking coal, found elsewhere adjacent to iron ore and limestone, is denied the West; yet its absence has engendered the greater need. The requirement of the West is not to be measured by standards elsewhere. The need is to discover possibilities under conditions that have been thought of with disfavor. Herein the proposed and untried processes that have appeared from time to time merit final and critical consideration. The blast-furnace must be thought of, not for what it can do at its best, but for what it could do if operated with the fuel that is to be had. The ores of the Pacific Coast must be more thoroughly examined and made better known. Transportation, for the movement of coke, must be encouraged by industry as a whole, and the local and national benefit from it fully recognized. The use of ore must be fostered in steel manufacture and in every local process where it can be employed; and until a way is found to produce sufficient pig-iron for local industry, local ores should be developed to supply this need. Beneath the high prices of the present time there can be read, in terms of past prices, the possibility of continuous and profitable future operation. In every phase of the industry the way is now cleared for expansion by the supreme commercial inducement for industrial activity. An iron industry in the West required, perhaps, nothing less than a world-war for its conception, but in coming it will find a permanent abode.

## Work of the Council of National Defense

A report was recently issued by the Council of National Defense setting forth the accomplishments of the sub-committees up to the first week of June. Among these achievements attention is directed to the mobilization of 262,000 miles of railroad for Government use, as well as the organization of the telegraphic and telephonic lines of communication, arrangement for the purchase of copper, lead and zinc for Government needs at reduced prices, thus saving large sums of money, the completion of the inventory for military purposes of 27,000 manufacturing plants, the creation of the Aircraft Production Board which has started to construct 3500 aeroplanes and to train 6000 aviators during the current year, the enlistment of reserve engineer-regiments for re-habilitating the railroads of France, and of another corps for improvement of the Russian railway service. The report is elaborate and reveals that the work of organization has been carried out so that definite results in providing the necessary supplies have been obtained. This has advanced to a point that will obviate the scramble for material that characterized the opening months of the War in France and England, and which gave an opportunity for shameless extortion and for graft through long chains of middlemen who exacted burdensome commissions. An orderly mobilization of the country's resources is in progress, with the co-operation of an army of producers of raw material and of manufacturers working in a well-unified effort toward the desired ends. In the matter of small arms and rifles arrangements have been concluded for supplying 1,000,000 men, but the work of manufacturing artillery has not proceeded so far with the exception of gun-forgings which are now being made. On the other hand sources of supply of artillery and accessories have been definitely found, and bases for contracts have been arrived at. Armored cars in large quantity are being manufactured, and an increased output of machine-guns is assured.

In coming to an agreement for the manufacture of aeroplanes the committee on aircraft has acted as mediator between the Wright-Martin Aircraft Corporation and the Curtiss Aeroplane Co. and has arranged a satisfactory basis of settlement of the patent controversy that hampered the operations of these competitors, thus leading to friendly co-operation for the welfare of the country. This has been accomplished by a legal cross-licensing agreement. The preparations for efficiency in this branch of the service give promise of realizing the expectations held by many as to the vital contribution of aeronautics toward the winning of the War. The medical service has been thoroughly organized under the general supervision of Dr. Franklin H. Martin of the Advisory Commission, with Dr. F. F. Simpson in direct charge. This Board is taking energetic measures for safe-guarding the health of the recruits to the Army and Navy.

One important step in the work of the Council of National Defense has been to create an Inter-departmental Advisory Committee to co-ordinate the efforts of the many special committees so as to obviate reduplication, and to serve as a sort of clearing house so that the different committees may without loss of time be able to secure any information and material needed for their specific purposes. A very brief statement is given of the activities of the Navy Consulting Board, which, however, has made important contributions toward the solving of some of the more pressing problems. Being the oldest of the Boards it is to be expected that it should display early efficiency. The Commercial Economy Board has attacked some important problems in conservation by undertaking to cut out many of the enormous costs in the delivery of goods to individual consumers. This has become a most wasteful practice in American retail trade, and the committee has secured the co-operation of leading merchants and Boards of Trade throughout the country to effect a reform in this particular, and also to avoid excessive costs in wrapping and packing, and also in the distribution of catalogues and circulars. The Committee on Coal Production, under the chairmanship of F. S. Peabody, of the Peabody Coal Co. of Chicago, has been doing good work in assuring supplies of fuel for the Navy, but since the date of this report the Federal Trade Commission has made a special report to Congress indicating the need of suitable action to provide for Government control of the sources of coal supply and of transportation systems so as to prevent interruption of manufacturing in the manner that so seriously embarrassed all branches of industry last winter.

Few portions of the committee-work have yielded such far-reaching results for aggressive as well as defensive purposes as the National Research Council, under the direction of George E. Hale and R. A. Millikan, who represent the highest ability of the country in physico-chemical research. This committee is working on means for detecting submarines and mines, in the perfection of range-finders, detectors for invisible aircraft and sapping parties, wireless apparatus, military photography, new explosives, and the prevention of corrosion and electrolytic action on the hulls of vessels.

Raw materials, minerals, and metals are under control of a committee headed by Bernard M. Baruch, and it has organized the field with regard to alcohol, aluminum, asbestos, magnesia and roofing, brass, cement, chemicals, coal-tar by-products, copper, lead, lumber, mica, nickel, oil, pig-iron, iron ore and lake transportation, rubber, steel and steel-products, sulphur, wood and zinc. Co-operative committees have been formed under the foregoing headings. Several of these committees maintain representatives in Washington in order to keep in close touch with the executive departments of the Government, and the chairmen of all of the co-operative committees visit Washington from time to time and get in touch with the Departments with which they have to deal in an endeavor to become acquainted with their requirements and specifications. While those committees were formed to

mobilize the industries mentioned and to act only in an advisory capacity, experience has shown that they have been of great immediate value to the Government in perfecting early deliveries and in securing prices below market-quotations. The concrete accomplishments of the Committee on Raw Materials, Minerals and Metals, may be itemized as follows: (a) 45,000 lb. of copper has been offered to the Government by the copper producers, acting at the instance of this committee, at an approximate saving to the Government of \$10,000,000; (b) The co-operative committee on zinc has contracted for about 25,000,000 lb. of zinc at about two-thirds of the market price, and is prepared to use its efforts to effect still further savings on the vast quantities that must be purchased; (c) Through the co-operative committee on steel the Navy Department contracted for several hundred thousand tons of ship-plates and other materials at great concessions. When ship-plates were selling at \$160 per ton, the Navy bought them at \$58 per ton; (d) The co-operative committee on aluminum purchased for the Government its requirements in aluminum at 27½c. per pound, when the regular price to large purchasers was 38c., and the price in the open market was 60c. per pound; (e) The co-operative committee on chemicals is now engaged in negotiations with the fertilizer interests of the country to stabilize and lower prices; (f) The co-operative committee on oil has closed contracts, for the delivery of oil to the Navy, at satisfactory prices. None of the foregoing committees is exercising executive functions, but each has advised with and assisted the executive departments of the Government in the purchase of their supplies.

CUPEL-ABSORPTIONS with low-copper, in tests made by Frederic P. Dewey, given in the Trans. A. I. M. E., varied from 0.23 to 0.33 mg., and on the high-copper from 0.24 to 0.34 mg., but there was a decided preponderance of low absorptions with low-copper and high ones with high-copper. The average absorptions were:

	Mg.
High-copper .....	0.2991
Low-copper .....	0.2773
Difference .....	0.0218

In order to keep the conditions the same, more lead and a higher temperature were used on the copper than were necessary, but the test clearly shows that copper increases the cupel-absorption. The same fact is also shown in a general way by 26 rows of cupels with copper in the ends, but without copper in the centres. The copper was alloyed with silver and two proportions of copper, 62.5 mg. and 125 mg. were each used with 4, 5, 8, and 10 gm. lead. The end-cupels yielded 9.33 mg. gold, and the centres 4.12, or 0.545 mg., less than half of the ends.

INFLUENCE OF BASE METALS in gold-bullion assaying, by F. P. Dewey, are summarized in the Trans. A. I. M. E. as follows: In small amounts, Zn alone has no effect upon the cupel Au. In large amounts the Zn-Au-Ag

alloy is formed, comes to the surface, and carries Au to the cupel. A tendency to do this occurs when small amounts of Zn are cupelled with large amounts of Pb. In all the comparative tests Cd showed a distinct protection of the Au, even when Zn was also present. The presence of Cu *per se* directly increases the absorption of Au, but its effect is intensified by the higher temperature and the larger amount of Pb required. The effect of Pb varies greatly with the surrounding conditions. The presence of Ag is a good protection to the Au, but may be overbalanced by other conditions.

## Need of Chemical Research

No amount of warning on the subject of the importance of pure chemistry seems to have the slightest effect upon American opinion. It has been dinned into the ear of our public that Germany owes her triumphs in the field to her pure chemistry. Our failure to profit by the warning, observes Dr. L. Charles Raiford in a recent address before the Chemical Department of Oklahoma University, is due to a typically American mental attitude toward what so many of us are pleased to call 'applied science.' Many highly intelligent educated people do not understand the meaning and the value of research, and hence they call it theoretical and impractical. Their cry is for that magic thing called 'applied science,'—for something 'practical.' They fail to recognize the fact that there can be no applied science until there is science to apply. Was Roentgen thinking of the extraction of bullets, the reduction of dislocated limbs, or the setting of broken bones, when he worked his way to the finding of the famous rays? By no means. Again, did Helmholtz have in mind the prevention of eye diseases or their cure when he worked out the principle of the ophthalmoscope? Not at all. Was Cavendish thinking of providing food and war munitions when, more than a century and a quarter ago, he read his paper to a learned society on the fixation of nitrogen. At this moment the republic is clamoring for preparedness, with no perception that the preparedness of the foe is chemical—based on the pure chemistry of the research-worker. Here in our own land cheap fertilizer must be furnished in times of peace, and nitric acid and other materials for explosives in time of war. The real problem is to furnish the means—pure chemistry—by which this programme can be carried out. Two specific requirements confront us. First there must be adequate training in the fundamentals of chemistry, and second there must be opportunity for chemical research. Now, if you ask the first person you meet, or if you get the opinion of the influential citizen, he is apt to tell you that the chemist is a man who can analyze substances. Do we stop to think of pure chemistry when we read the headlines in the newspaper bearing a wireless message flashed across the ocean? Who, as he steps into his automobile or watches the movies, thinks of the chemist in his research laboratory? Chemistry! It will win the War; and no American, befogged by 'applied science,' can get that truth into his head.

# Mill-Tests v. Hand-Sampling in Valuing Mines

By MORTON WEBBER

Two methods may be chosen by the mine-valuer in the examination of a mine. Much has been written as to which is the better. In fact, so divergent have been the views expressed that there has developed what really amounts to two schools of thought. The one is the practice of basing the report of an examination on hand-sampling and the other is the process of procuring for the purpose of a mill-test a representative sample of the expected profitable ore of the mine.

During a recent discussion in the MINING AND SCIENTIFIC PRESS, I was asked by the editor to contribute my opinion as to the method I regarded as the more reliable, especially as applied to the examination of large low-grade ore deposits. There is no doubt in my mind that the choice of either method should depend primarily on the ore-structure. The size of the deposit, as a factor in the choice of method, is only of importance in relation to the cost of examination. I believe each mine is a problem unto itself. My experience has taught me that there is generally a particular method of sampling that will possess decided advantages over any other method of examination. This may be a combination of both methods or only one, or it may be the application of one method applied to the mine-workings as a whole, with a variation or combination centralized on a certain part of the mine to throw additional light on some specific feature.

The more experienced the engineer the quicker and more accurately will he decide on the method most expedient to obtain the essential data. In other words, the proper choice of the examination programme, for a particular case, as against rule of thumb, is the criterion of the valuation specialist as against the general practitioner. There is also another point. The terms of purchase may govern the method of examination. I suggest that this feature has been considerably overlooked in discussions on this subject. It was only through somewhat varied and extensive examinations on behalf of a purchaser—an important corporation—in the course of which I had to negotiate for options prior to examination, that I realized the importance of this additional burden on the valuing engineer. In recent years the mine-valuer has had to become a consultant on mining finance generally, and particularly on the method of payment in the purchase of mining property. When a very young man, I was introduced to the famous Cecil Rhodes, and he indicated that there would always be more than ample room 'at the top' for the mine-valuer who could co-ordinate natural business ability with mine-valuation.

The following description of three examinations conducted under my direction may be of interest. For reasons that will be sufficiently obvious, I cannot furnish the names of the properties, so I shall call them the Red,

White, and Blue mines, and they will be dealt with in this sequence.

The Red mine represents a case in which, because of the structural nature of the orebody, I considered a mill-test was the proper method of examination. The mine was subjected to a preliminary sampling prior to the mill-test in order to determine the locus of the shoots and a more detailed sampling was undertaken subsequent to the procuring of the representative shipment. I give this example, therefore, as an actual case of a combination of the two methods. The White mine, on the other hand, represents a case in which the orebody was uniform in value. In other words, the ore was not localized in what

THE SAMPLING CREW THAT CUT 6½ TONS OF SAMPLES IN 30 DAYS AT THE WHITE MINE

are generally regarded as 'shoots,' nor did there exist the variation in value and mineral characteristics between one shoot and another, one of the principal reasons for applying the mill-test in the case of the Red mine. The Blue mine, finally, represents a case as mentioned above, where it was desirable to apply ordinary sampling over the general workings, but where a representative shipment was obtained from a certain part of the mine to throw additional light on a specific feature. This was also a case where the terms of purchase governed the method of examination.

The ores of the first case (Red mine) contained gold, silver, and lead. Briefly, the mine was composed of several irregular ore-shoots occurring along a fault-zone in granite. The thickness of the zone was about 50 ft. and considerable brecciation and post-mineral faulting were evident. The shoots were located on the hanging wall and also on the foot-wall. Ore-shoots were also encountered running diagonally from wall to wall. An important feature was the marked difference in the mineral characteristics of the ore-shoots. One shoot was clean

lead-silver ore, carrying about 12% lead and approximately 10 oz. silver. Another shoot was a heavy iron pyrite (about 7 cu. ft. per ton), carrying an unimportant quantity of lead and averaging about \$17 per ton in gold and silver. A third shoot was a friable fine-grained iron pyrite, carrying about 50 oz. silver and about \$10 in gold.

This was a difficult type of mine to examine. Evidently the examination of the property involved a treatment problem. I believe that the specialist in valuation will assume too much if he attempts to encroach upon the domain of the not less important specialist on metallurgy. It is, however, the duty of the valuing engineer, if doubt exists as to the best method of treatment, to procure a shipment from the mine-workings, representative of conditions as they exist at the date of examination. An important point is to submit to his client a clear opinion stating how far such a shipment is likely to represent the ore upon which the future life of the enterprise will depend. I considered it my duty therefore to obtain this representative shipment. If the shipment thus obtained differed from the product of the mine under actual operation, the error lay with me. If it did not differ, but the metallurgical process was defective, or a failure, the blame lay with the metallurgist.

In accordance with my observation that there is generally 'one best way' to conduct the examination of a particular case, it was evident that the solution did not lie in shooting down a composite shipment from each of the stopes. At the outset there was one factor outstanding in relation to the subsequent executive or administrative features. This was that the widely varying types of ore-bodies, could be mined separately, if desirable. Therefore it was important to get the representative shipment to the metallurgist in such a way that this administrative feature remained undisturbed. In other words, it was important that the metallurgist could deal with each stope or individual source of ore-supply separately, that he could eliminate the ore from certain stopes at his discretion, or make such combinations as he desired, in addition to dealing with the average ore of the mine, as a whole.

The method of examination to cover these features was as follows. It was necessary from the start to decide on a pre-determined weight per foot sampled. In order to obtain a representative shipment of the average product of the mine, it is important that each stope should contribute its *representative* weight. If every care is not exercised in this particular, it will throw the representative shipment out. I am convinced it is here that most mill-tests go wrong. In the majority of mill-tests that have come under my observation, little attention was paid to this point, which I regard as a most critical feature in an examination. In this case, I decided on a foot-weight of 500 lb. per foot. What the foot-weight should be depends on the individual case. The main point is that once it is chosen, the foot-weight should be rigidly adhered to.

It was impossible to break down the ore from the stopes in definite proportion to their width. A round of

shots from a stope eight feet wide would break 6000 lb., or 50% above the composite proportion, whereas another stope five feet wide would break 5000 lb., or 100% above its composite proportion. These simple figures will illustrate where the usual mill-test fails. In all cases I made certain before firing the rounds that the shots would break more rather than less than the required foot-weight. This was to avoid going back over the same area for the deficient portion, as such a step would be, in effect, tampering or unnecessarily introducing the personal factor. Once the sampling programme is laid out, this should be avoided as much as possible.

When the product was obtained from a particular stope, it was broken to a convenient size for thorough mixing. After being thoroughly mixed, the over-weight was discarded. The mixing was done on a mixing-floor arranged for the purpose. As an additional precaution against error, great care was exercised in removing the over-weight. If the sample was found to be, say, 20% over-weight, the whole sample was hand-shoveled to another part of the mixing-floor. In the transfer every fifth shovel was discarded. This was introduced to anticipate an error in event of the sample being insufficiently mixed. The samples from the various stopes were numbered according to the stope from which they came.

In the above examination, therefore, I accomplished what I set out to do, namely to obtain a shipment of the workings as a whole that would represent the average grade and also the average mineral characteristics of the mine, as a whole, if the stopes were operated simultaneously. I obtained the sample in such a way that each stope could be dealt with separately by the metallurgist in his research work, as reflecting the underground administrative policy, should it be desired to keep the product of the stopes separate. I also found, by comparing the result of the hand-sampling with the assay of the composite pulp from each stope, the sampling error for each class of ore—a most important feature in a mine of so divergent stope characteristics. By comparing the assay of the pulp of the total shipment with the subsequent hand-sampling, I obtained also a valuable index of the sampling factor of the mine as a whole.

The White mine represents an entirely different case. It contained a large low-grade gold deposit. It was known that the ore of this mine was simple in treatment. The factors of existing and expected quantity of ore and the average grade were therefore primary, and the metallurgical problem was relatively subordinate. This, coupled with the fact that there was no localizing of the gold into shoots and particularly into shoots of dissimilar mineral characteristics, made an examination by means of a mill-test inexpedient. In fact, I characterize this case as being essentially a straight hand-sampling job. The sampling was conducted as follows, as quoted from the text of my report:

"The workings were sampled throughout the supposed orebody at intervals of 10 ft. In the raises and winzes sectionalized sampling was employed wherever desirable. In view of the low tenor of the ore, it was important that

sampling should be accurate. An error that may be unimportant in medium or high-grade ore becomes a large proportion of the total content when the ore is low-grade. The sampling and cutting down was performed as follows: The original cut averaged about 10 lb. per foot. This mine-sample was reduced on the surface to pass half-inch holes. The entire sample was then mixed on a mat for a minimum of 5 minutes. Great care was taken to insure each sample being mixed for at least this period. A clock was furnished for this purpose. The work was under the constant supervision of a trained engineer. His duties were confined to this department. After the sample had been mixed, as described, it was then reduced by a Jones sampler, when it was ground to pass quarter-inch holes. The sample was then mixed again on a mat for 5 minutes, when it was cut down by a Jones sampler to approximately one pound and a half. The sample was then, without further reduction, ground in its entirety

check himself, which he did to 20 cents. A flux and slag assay was run every day."

A feature of this work was the heavy sampling. I am not an advocate of cutting a light sample where it is necessary to obtain the highest possible accuracy under practical sampling conditions. It may be of interest to state that while engaged by a client to search for mining property, it was my custom to make a preliminary sampling of a mine and then to option the property before I undertook a final sampling. In the preliminary examination I always cut light samples, about  $1\frac{1}{2}$  lb. per foot, because I was not equipped to take heavy samples. In cases that withstood the 'preliminary,' and final sampling was undertaken, I found frequently that lower results were recorded by heavy sampling.

In the sampling of this mine it was desired to average 10 lb. per foot. In my experience this is the weight that gives the highest accuracy compatible with convenience.

THE POP-SHOT SAMPLES TAKEN IN THE BLUE MINE

to pass 80-mesh, when it was again mixed for 5 minutes, prior to being split in duplicate. Great importance was attached to mixing. By this process each sample in its reduction from the original, which averaged between 50 and 60 lb., had been mixed for at least 15 minutes.

"In order to check the accuracy of the sample as cut in the mine and also in its reduction to duplicate pulps, two systems of checking were employed. A series of cuts was re-cut and given different numbers from the original tags and were treated in every respect as separate samples in subsequent reduction and assay. The series checked to 25 cents per ton. This checked the accuracy in the cutting of the sample and its subsequent reduction. The sampling work was also checked by the assay of a series of duplicate pulps. The assays were in duplicate and they checked with the original pulps, as assayed at the mine, to 20 cents. The assaying at the mine was checked by a third system whereby a group of pulps that had been assayed were put into fresh envelopes and different numbers attached. The assayer was thereby caused to

It was my object, if possible, to have the average of my sampling within 30 cents per ton of the mill-heads of actual operations. The photograph will indicate the size of the original mine-samples, and it will also illustrate the size of sampling crew necessary on a fair-sized mine to do a job where much heavy sampling is necessary. In this case, about  $6\frac{1}{2}$  tons of samples were cut in 30 days, and the samples in the photograph represent about one day's work.

The Blue mine—the third mine—represents a hand-sampling job where a mill-test was made covering a part of the workings to obtain special data. This example represents a case where the terms of purchase governed the method of examination. The property was a silver-gold mine, the silver being in the form of argentite. The vein was about 15 ft. thick and the country-rock was andesite. The vein outcropped for nearly two miles. The larger portion was controlled by the property under examination. In the early history of the operations ore had been mined and shipped from several shafts situated

at irregular intervals along the enormous outcrop. That these surface shoots did not persist in depth was evidenced by the fact that one after another these small operations had been abandoned. The property had then been lying idle for a period of years until an optionee sunk a shaft through one of the old workings, passed through what, for simplicity of expression, could be called a barren zone, when a profitable ore-shoot was again encountered. A level was driven to determine the length of the shoot, which was, in round figures, about 300 ft. As the vein was very hard, the optionee drove this level along one of the walls and drove cross-cuts through the orebodies at intervals of 50 ft. These cross-cuts indicated the width of the shoot to be about 10 ft., and of profitable grade. The shaft was then extended with the intention of demonstrating the shoot at the 600-ft. horizon and at further depth. The shaft was in the foot-wall. The fact that the orebody on the 500-ft. level was only demonstrated by cross-cuts at 50-ft. intervals should be noted, because this influenced the conduct of the examination, as I shall attempt to show.

The above was roughly the situation at the date I made my examination on behalf of a new purchaser. The sketch will demonstrate the position of the workings. Under the terms of my client's option, about one-third of the purchase price fell due in about four months from the commencement of my examination. I mention this as I have pointed out that the terms of purchase may govern the conduct of examination.

The speculative attraction was briefly in finding a new and distinct ore-shoot at depth below a surface shoot that had been exhausted. I considered that if the lower shoot could be demonstrated to be of importance, and in itself was likely to amortize a fair proportion of the purchase price, it would make the development of the lower horizons of the other old surface-workings an extremely interesting development speculation. This was how I regarded the project at the date of my preliminary examination. There was still ore left in many of the old workings, but I regarded such ore as merely a bonus of some importance, in case we took the property. I regarded the standing ore as only of subordinate importance as an index of the future worth of the mine. The latter feature was the major item of interest to me as representing a purchaser with ample financial resources intending to put the enterprise on its feet. In order to ascertain the grade of the new shoot, I decided to put 'pop-shots' in both sides of the cross-cuts, for I considered there were insufficient faces to sample over the area involved on the 500-ft. level to rely sufficiently on the law of average. In other words, it was essential to have each sample represent the place from which it came as accurately as possible. Therefore I fell back on the principle I have found from experience to be the best (as employed in the White mine, and at variance with the advocates of the light sample), namely, heavy sampling. Only in this case I obtained enough ore for a mill-test, for the foot-weight of each cross-cut was about 120 lb. per foot. The ore from each cross-cut was sacked sep-

arately and reduced separately to duplicate pulps. The accompanying photograph will indicate about half the shipment on its arrival at the smelter. As in the case of the Red mine, the sacks were numbered in groups, depending from where they came.

The average of the cross-cut pulps and the assay of the pulp of the composite sample checked to exactly one cent. I mention this as indicating the care taken in mixing the sample before cutting down. This was done at the sampling-plant of a near-by smelter. This concern turned over to me some of their most experienced sampling crew. While these men were only the ordinary day's-pay employees used at smelters for sampling, they had been accustomed to this class of work for years. This and the use of the power-driven sampling-plant gave me every facility for accuracy.

I desire to call attention to a matter that may seem elementary. It is most important to mix a sample thoroughly before the 'first' cutting. Many engineers give too little care to this important stage. I cannot too strongly emphasize that the careful mixing of a sample *before* stage-cutting is commenced, is one of the most important factors in this work. For example, if a sample is cut before it is sufficiently mixed and the assay of the opposite quarters is in one case \$10 per ton and that of the other opposite quarters is \$12 per ton, it does not matter what care is exhibited in the subsequent crushing, mixing, and cutting, the above error at the 'fountain head' cannot be eradicated.

I shall now attempt to show wherein the terms of purchase governed the form of examination. By consulting the sketch of the horizontal projection, the probable position of the lower ore-shoot will become clear. The position of the shaft-bottom at the date of examination is shown in the sketch. I had considerable trouble in arranging for the delay of the first payment, about one-third of the purchase price, until four months from date of examination. As these were the best terms obtainable, I optioned the property, because I considered it would be possible by forcing the work to sink the shaft to the necessary depth and to cross-cut the workings at the intervening lifts and to extend drifts sufficiently to obtain a fair indication as to the advisability of exercising the option. I repeat that, if it was possible to demonstrate an important ore-shoot on this lower horizon, the enterprise would present an attractive possibility of finding recurring ore-shoots by developing the lower horizons of the other surface shoots distributed at irregular intervals along the long length of outcrop. The point, therefore, was to ascertain, if possible, the prospect of developing such a shoot. Getting an organization started on a job like this and performing the work, which had to be rushed, was a matter of considerable expense. It was important therefore to forestall a situation which might arise in four months, namely, of having insufficient data on which to advise my client as to whether the large payment that would then mature should be made or not. If such a situation arose, my client would have been in the unfortunate position of having to ask for a re-

arrangement of terms. In the event of refusal, this would have meant either assuming a big risk, or dropping out and leaving improvements and the additional development to the benefit of the owner. To avoid this, a double crew under the charge of an assistant was employed to drive a cross-cut from the bottom of the shaft to penetrate the orebody. By referring to the sketch, it will be noted that the shaft is in the foot-wall and approximately in the centre of the lower shoot. The cross-cut is marked X. In this way the shoot was penetrated from wall to wall. The orebody at this intersection proved quite unprofitable. On the basis of these data, I put the position frankly before the owner. I explained that it was possible that the cross-cut X might be situated in a barren patch in the orebody. While I did not demand a modification of the total price, I insisted that the first payment be delayed to give my client time

could have been cheaply sampled on day's-pay. The organization would have been on the ground in any case.

The foregoing will indicate that the method of the examination of a mine is a matter of the diagnosis of the individual case. In the absence of an actual example it is dangerous to generalize as to whether hand-sampling or mill-tests are preferable. It may be assumed, however, that in the majority of cases mill-tests should be limited to ascertaining the sampling-error. This can be obtained by comparing the average of successive sampling of the stope-faces during the removal of the ore for the mill-test with recovery plus tailing-loss. Therefore the valuation of the ore reserves of a mine and the sampling of the various points critical in the estimation of the future possibilities of the enterprise should depend in most cases on hand-sampling. This may be corrected by procuring a sampling-error for various

to determine by further development whether the adverse evidence was local or general. The owner declined to concede the required modification, and negotiations terminated.

Shortly afterward the mine was examined on behalf of a new prospective purchaser, a large corporation. All the workings were sampled at 5-ft. intervals, shafts, cross-cuts, and old workings alike. Apart from the question of the fee of the valuing engineer, the cost of sampling alone must have been three times the cost of my examination including the cost of driving the cross-cut X. I mention this as an interesting example of how two engineers may view a proposed purchase from entirely different standpoints. I do not see what was gained by sampling the old workings at that time notwithstanding the probability that they contained some important portions of ore. As an index to the future life of the enterprise, I regarded their importance as purely subordinate. Had my client taken physical possession as the outcome of the examination centralized on what I regarded as the 'life extension' of the enterprise, the old workings

would have been cheaply sampled on day's-pay. The adjacency of mill-tests to each other will depend on the nature of the ore. In this way it may be possible to divide any ore deposit into zones depending on the engineering expediency of the particular case.

POTASH EXTRACTION from the materials entering into the manufacture of cement is increased by adding to the raw mix a calculated amount of calcium fluoride (fluor spar) which causes the potash to volatilize more readily as potassium fluoride. The flue-dust and fume are saved in the Cottrell apparatus, and the dust so collected is leached with water. The lime-salts present again react with the fluorine in the potassium fluoride, regenerating the insoluble calcium fluoride, which remains in the filter-cake and is returned to the kilns, while the soluble potassium salts are recovered by evaporation. This method of augmenting the yield of potash as a by-product in the cement industry was patented by Huber and Reith of the Riverside Portland Cement Co., Riverside, California.

# Flotation—The Butte & Superior Case—I

## Part of Argument by Walter A. Scott, for the Defendant

When we started out with this case we studied the patent suit and found that it sets forth no definite principle and contains no definite statement whatever, except that a new phenomenon came into existence when this young gentleman (A. H. Higgins) in London, in trying some experiment, reduced the quantity of oil to an amount less than 1%, and that this new phenomenon was a froth, a useful froth, a mineral froth, capable of wide utility. We proceeded upon that theory in the Hyde case, that the patent meant something and that it could only mean one thing. When the evidence was taken in the Hyde case we began to feel that we had come to the right conclusion and were upon sure ground, because Dr. Chandler, their expert, after quoting the statement in the patent that when the quantity of oil was reduced to less than 1% the mineral rises as a froth, added, "This is the foundation of the invention of the patent in suit". We had no refined theory there about soluble ingredients in the oils; we had nothing of frothing agents, of inert oils; we simply had 'oils'. And the foundation of that invention was said to be reducing that oil to less than 1%.

When the Hyde case was heard by this Court our presentation was simply an oral argument illustrated by one simple demonstration in a hand-manipulated test-tube. Our opponents produced an elaborate system of demonstration and experiment wherein they represented to this Court that all of the processes of the prior art, without exception, were failures. This was purely negative evidence, but we did not meet it by repeating the demonstrations before this Court that had been performed by our witnesses and by them described in their testimony; and quite naturally this Court was influenced by plaintiff's demonstrations, as I have always thought.

But the presentation of this case here in the past few weeks has served to emphasize the danger of reliance on merely negative testimony. They had learned to infallibly cause all of the suggestions of the prior art to seem useless, and, when put to practice, to end in failure. That such evidence should have no probative force is shown clearly to us by the fact that Mr. Higgins, the skilled demonstrator of this plaintiff, was obliged to try six times before he could concentrate Butte & Superior ore in this Court by the very process of the patent in suit. These demonstrators come here, they exhibit to this Court the processes of the prior art with every inducement, motive, and desire to make them fail, they desire this Court to believe that that is evidence that these things cannot be made to succeed. They then come before this Court with this elaborate setting of failure within which to cause their invention to sparkle and try the invention of

the patent in suit upon the Butte & Superior ore that the Butte & Superior company has been able to treat successfully for years, and after five successive attempts to apply that invention to that ore, they meet only with failure. How do they account for that? How does that harmonize with their efforts to prove the failure of the prior art by exhibiting these ludicrous, these studied attempts at failure to the Court? Do they think, with every motive, inducement, and facility to make the process of the patent in suit successful, it does not bear at all against the process of the patent in suit to have it fail five times after elaborate rehearsal and preparation, but that it is convincing proof when studied attempts to cause failure of the prior art processes do eventuate in failure?

When we appeared before the Court of Appeals in the Hyde case we made demonstrations of the prior-art processes, made them in strict conformity with the directions of the prior art. Now, in practising flotation there is very little to follow either in the patent in suit or in any of the prior-art patents. What has made flotation a success today is not found in any of these, much less in the patent in suit. The only essentials that we find in the patent in suit are the grinding of the ore, its admixture with water, the addition of oil and agitation. And by 'oil,' as the prior-art patents say, is meant any substance which will adhere selectively to the metalliferous mineral. Therefore 'oil' is a generic term including, as stated by Cattermole and other patentees, all of the substances used in the prior art, oils proper, phenol, and creosol, which are soluble, and which this plaintiff seeks to make the subject of another patent ten years later, oleic acid, and, as Mrs. Everson says, all animal, vegetable, and mineral oils. Now, we have these four items, and the illustrations which we presented before the Court of Appeals in San Francisco embodied these four items, and these four items are stated with no more precision in the patent in suit than in the prior-art patents.

Of course this plaintiff can go to the prior-art patents and say they don't tell us how fast to agitate; that they say nothing of this violent agitation practised today. They do not in terms, and neither does the patent in suit. None of them have anything but descriptive words. And the link that I claim is lacking in this case is the link which, if the position of this plaintiff is good, is something which shall connect this violent agitation of today with their patent. There is none. Their patent says, "thorough agitation." Other and older patents say "thorough agitation" (Everson patent, p. 2, line 100; Kirby patent, 809,959, p. 1, line 73); and some of them say "violent agitation" (Kirby patent 809,959, claims

1, 2, 3)—mere descriptive language in all of them. Kirby also refers to vigorous agitation (patent 809,959, claim 9). The California Journal\* refers to thorough agitation to produce a foam or froth. And it is my contention that unless in the patent itself there can be pointed out something more directly connecting modern flotation with that patent than with these other prior-art documents, this plaintiff has no right to claim that this patent has disclosed flotation to the world and that the world owes flotation to this patent.

The process has developed during all of these years, to be sure, but the patent in suit is a disclosure to the world of only what is in it, and that patent should, in all justice, stand on the same footing as all of the other prior-art patents.

Therefore, I say that when we did these demonstrations before the Court of Appeals in San Francisco we followed the prior art with precision. We derived nothing from the patent in suit that was not equally well disclosed in the prior art, namely, the grinding of the ore, the addition of water to make a pulp, the addition of oil, agitation and the resulting froth. The Court of Appeals, looking at these things, came to the conclusion that there was nothing in the disclosure in the patent in suit, and so decided.

Now we come to the Supreme Court, where the definition of the alleged invention met its first alteration at the hands of counsel for plaintiff. The patent began to take on the protective coloring demanded by its new surroundings. In the course of his argument before the Supreme Court Mr. Justice McReynolds asked Mr. Kenyon when in the process of reducing oil the invention came into existence, to which Mr. Kenyon replied, "at about one-half of 1% of oil." Mr. Justice McReynolds then asked whether before getting to one-half of 1% there was any invention, to which Mr. Kenyon replied that the invention was not reached, he should say from certain figures in the record, until about one-half of 1% of oil was reached. Mr. Justice McReynolds followed with a question as to whether there was any invention at 1%. Mr. Kenyon replied "No," but that the invention began to come remotely at one-half of 1%. The final question of this colloquy put by Mr. Justice McReynolds was an inquiry as to whether when a float has more than one-half of 1% of oil it does not infringe, and Mr. Kenyon replied that it did not infringe.

Now, before the Supreme Court we presented our demonstrations of the prior art as we have in the case at bar before this Court; and the products resulting from these prior-art processes were absolutely indistinguishable, indistinguishable to the eye and to analysis as to the amount of metal recovered, as shown by the testimony of the witnesses whose demonstrations were repeated, but we were there met by still another argument, or assertion I should say, and a false assertion. We were met by the assertion that while these froths look alike, while opposing counsel themselves said they couldn't tell them apart

by looking at them, still, your Honor, they said to the Supreme Court: "These things cannot be done in a mill."

THE COURT: You told the Supreme Court it could, I suppose?

MR. SCOTT: I told the Supreme Court, your Honor, that the record did not enable me to answer the question. That was my precise answer. I would like to have told them what your Honor suggests, but the record contained no support for such a statement.

THE COURT: Well, did you suppose that the Supreme Court instead of taking the Hyde record would take the statement of counsel if they were made? Of course, this is outside the record.

MR. SCOTT: I would not have expected them to accept as a fact a statement of counsel in the absence of any testimony of any witness. It did not appear to me to ask them to accept my statement as a statement of fact on these operations.

THE COURT: Their statements, which you say you made, don't you suppose after all that this decision was rendered, not on the statements of counsel nor the claimed estoppel, but upon the record in the Hyde case? Can we go back of that?

MR. SCOTT: Well, if it was decided upon the record in the Hyde case, your Honor, the suggestion of opposing counsel that this could not be done in a mill might have been considered argumentative by the Supreme Court, and then looking at the Hyde record the Court found no evidence that it was done in a mill. They found simply the testimony regarding laboratory demonstrations.

The reason that in the Hyde case we could not show any operations in a mill with any large quantity of oil was that at the date of the trial of that case, seven years after the application for the patent in suit, the process was not being carried out in any mill in the United States excepting the Butte & Superior mill, and at the time the testimony was taken in the Hyde case the process was of doubtful utility even there, as testified to by Mr. Frank Janney, who said in this Court that it was not until the spring of 1913 that the officials of the Butte & Superior company became convinced that flotation would be a success. So, on that state of facts, it was an absolute impossibility for such evidence to be produced.

Now, in deciding the Hyde case I think we find in the opinion of the Court abundant evidence that Mr. Kenyon's statement had great influence upon the Court, this statement about no infringement below one-half of 1% of oil. I will quote eight or ten lines of it:

"Convinced as we are that the small amount of oil makes it clear that the lifting force which separates the metallic particles of the pulp from the other substances of it is not to be found principally in the buoyancy of the oil used, as was the case in prior processes, but that this force is to be found, chiefly, in the buoyancy of the air bubbles introduced into the mixture by an agitation greater than and different from that which had been resorted to before, and that this advance on the prior art and the resulting froth concentrate so different from the

\*Referring to the article by three students in *The California Journal of Technology*. See M. & S. P., July 31, 1915.—EDITOR.

product of other processes make it a patentable discovery as new and original as it has proved useful and economical." And in the closing passage of the opinion, the Court referred to the critical proportion of oil.

Now, analyzing these passages, we find that this plaintiff in this Court has repudiated every single one of these elements upon which the Supreme Court based its finding of validity. The plaintiff now claims the use of any amount of oil which produces a certain result. The Supreme Court in this passage which I have just read says:

"Convinced as we are that the small amount of oil used makes it clear"—

Now plaintiff discards the small amount. Any amount that produces a certain result, they claim.

Then their witnesses go further in the repudiation of this passage from the Supreme Court opinion. The Supreme Court opinion says that

"The small amount of oil used makes it clear that the lifting force which separates the metallic particles of the pulp from the other substances of it is not to be found principally in the buoyancy of the oil used."

Mr. Higgins now says of prior-art quantities of oil that they do result in this 'air-froth' of the patent in suit. Mr. Higgins says that 20 lb. of oil will only float 2 lb. of mineral. Of course, that is negligible, showing that that amount of oil cannot account for anything. Mr. Higgins says the demonstration in this model pyramid machine that was exhibited in the grand-jury room was a demonstration of the process of the patent in suit. Now, in that operation there were 42 lb. of oil used per ton or 2.1% of oil. That is a prior-art quantity of oil and that is a quantity of oil which the Supreme Court was prevailed upon to believe must result in oil-buoyancy. The Supreme Court says that the small amount of oil in this patented process makes it clear that the lifting force is not to be found principally in the buoyancy of the oil as is the case in the prior processes. The Supreme Court was prevailed upon to believe that it is the reduction of the amount of oil below 1%, or one-half of 1%, that led to the distinction between the mineral being lifted by the buoyancy of air and its being lifted by the buoyancy of oil. As a matter of fact—

THE COURT: I was just going to observe—of course, there is no impropriety in your argument—but don't you think that ought to be addressed to the Supreme Court in a motion for rehearing? Could this Court take it into consideration?

MR. SCOTT: My idea of that is this: Opposing counsel referred to the doctrine of *stare decisis*. But the state of facts is absolutely different in this case. Even counsel who told the Supreme Court that there was no infringement, with over one-half of 1%, now comes to this Court and says there may be infringement with any percentage of oil.

THE COURT: I was just trying to make it clear to myself how far your argument ought to weigh with the Court, that was the idea. You may proceed.

MR. SCOTT: The statement in the Hyde case seems to me to be plainly a judicial admission that there is no

invention with over one-half of 1% and no possible infringement with over one-half of 1%, and my point is that such a variance in the presentation of the matter by counsel, to say nothing of the variance that is involved in the testimony of the witnesses, removes the decision of the Supreme Court from any possible interference with the exercise of judgment *de novo* in this case now before this Court. I fail to see how we could make the Supreme Court case a precedent, the facts and testimony and admissions of counsel being so different.

THE COURT: I understand your attitude.

## Rapid Shaft-Sinking

Recently rapid progress was made in sinking at the Gadsden shaft, in the Warren district, Arizona. Through the courtesy of J. K. Hooper, superintendent of the Calumet & Arizona Mining Co., at Jerome, Arizona, some of the details of the work and the conditions under which it was accomplished are here given. The shaft has three compartments, two of which are for hoisting, being 4 ft. 6 in. by 5 ft. in the clear, one being for pumps, pipe-lines, and ladders, having a section 7 ft. 6 in. by 5 ft. in the clear. The shaft required an opening 21 ft. long and 8 ft. 6 in. wide. From the morning of May 8 to the morning of May 15, that is seven days or 21 shifts, the shaft was sunk 63 ft., and 12 sets of timbers, spaced at 5 ft. centres, with guides, ladders, and pipe-lines, were put in place. The work was done on company-account, plus a bonus for a footage exceeding 130 ft. per month. The distance usually carried between the timbers and the bottom was from 9 to 14 ft. The rock passed through was limestone, and it required from 26 to 34 holes for a round. The cut-holes were 10 ft. deep, the others averaging 7½ ft. The men worked three shifts daily, with 6 men on a shift. They shoveled the broken rock into buckets for hoisting to the surface. For the work of drilling four Ingersoll-Rand BCRW-430 jackhammers and one Sullivan DP-33 jackhammer-drills were employed, using ¾-in. hexagon-steel with cross-bits. Hercules 1-in. 40 and 60% gelatin-powder was the explosive used exclusively, the 60% powder being placed in the bottom of the holes. Triple-tape fuse and No. 8 caps were used, all shots being fired by hand, spitting in the usual manner. There was little water to contend with, nearly all of it being taken up by the fine rock with which it was hoisted in the buckets. During the week referred to a total of about 12 hr. was lost in blowing out smoke after blasting. The hoisting-equipment consists of a direct-motion, double-drum electric hoist, and an Ingersoll-Rand 'Imperial' compressor of a capacity of 888 cu. ft. of free air per minute.

RESEARCH into the constitution and character of cement by the U. S. Bureau of Standards has shown that alumina is apparently not essential to obtain the desired setting qualities, but it is necessary as a flux in the burning of the mix to make the clinker. Otherwise the manufacture of cement as now practised would be commercially impossible.

# Electric Blasting-Caps and Delay-Electric Igniters

By I. H. BARKDOLL

An electric blasting-cap is a special form of instantaneous detonator fired or exploded by an electric current. The delay-electric igniter is a cylindrical copper tube into one end of which the necessary wire, plug, and other parts are inserted, while the other end is crimped upon a piece of ordinary fuse with a blasting-cap attached. The difference in the length of the fuse designates the different delays, that is, two, four, six, and eight inches of fuse gives one, two, three, and four delays. They are made waterproof with well insulated wires and long waterproof rubber covers for the igniter, fuse, and detonator; this is further waterproofed by a heavy coating of gutta-percha over the entire length. In blasting in a drift, shaft, or raise, it is necessary to blast each round of holes in sections or in rotation. The difference in the length of the fuse used with the electric igniter, explodes the charge in the proper sequence. There is practically no limit to the number of charges that can be fired in sequence by this method. Under most conditions there is nothing to be gained by dividing the round of holes into more than three or four sections. This permits of cuts, relief, and corner-shots.

Electric blasting-caps and electric igniters have been developed for such conditions so that these four classes of shots, or more, may be fired in rotation with a single set of wiring and with but one application of the electric current. The different delays are so constructed that there is a brief lapse of time after the current is applied before the first delay explodes and a longer delay before the second delay explodes. It should not be understood that all first-delay caps explode simultaneously, but the variation in time is very little. This variation is caused by the irregularity in the burning-time of the fuse and the slight difference that may occur in the fuse-lengths. Connecting-wire used in their manufacture is of insulated copper, No. 20 gauge. The ends of the connecting-wires must be scraped bright before the connections are made, and the joints should not be permitted to lie in water or on wet ground. If this cannot be prevented, the joints should be covered with insulating tape. The wire for connecting blasting-caps and other electric detonators to the blasting-machine is known as the leading-wire. It is of insulated copper wire, may be furnished in desired lengths, and should always be long enough to keep the blaster well out of the danger-zone. Leading-wires are of two classes, single-strand and duplex. Duplex is made by bringing together two insulated copper wires with an outer insulation, thus giving a return-circuit that may be handled as a single wire. The single strand would be the same two wires, but not bound together, requiring the handling of two wires separately.

There are advantages and disadvantages in the standardization of either type of leading-wire. All leading-wires 300 ft. long, or less, should be solid wire of a gauge not smaller than No. 14; from 300 to 400 ft., No. 12 gauge solid; and for lengths greater than 400 ft., No. 10 gauge solid should be used.

Electric blasting may be accomplished either with a blasting-machine or with a power or lighting circuit. Blasting-machines are small portable dynamos used to generate the current for firing blasts by electricity. The downward thrust of the rack-bar converts muscular energy into electric energy, which is short circuited through a field-magnet for the purpose of building, intensifying, and storing the current until the end of the stroke, when the accumulated current is sent through the firing line. They are rated according to the number of electric blasting-caps they will fire when connected in series. There are five different sizes, known as two-post machines, No. 2, 3, 4, 5, and 6. No. 2 has a capacity of from 1 to 10 electric blasting-caps; No. 3 from 1 to 40; No. 4 from 1 to 60; No. 5 from 1 to 100; No. 6 from 1 to 150.

When operating a blasting-machine, set it squarely on a solid level place, connect the wires to the binding-posts, and screw down the wing-nuts tight, lift the bar by the handle to its full extent, and with one quick hard stroke push it to the bottom of the box with a solid thud, using both hands. Try to knock the bottom out of the machine. As the bar approaches the bottom it becomes more difficult to operate because of the building up of the current, but the speed of the thrust should not be diminished as the finish of the operation is more important than the start. A galvanometer is a small instrument used by some blasters to determine whether a blasting circuit is open or closed. An open circuit is one that is broken or faulty, due to poor connections or to broken wires. Galvanometers are also useful to indicate the existence of leaks or short circuits. It is a magnetic device which, if the circuit is closed, that is, if there are no faulty connections nor broken wires, moves a pointer across a scale, due to the flow of electric current through the closed circuit. In making the test with a galvanometer, connect or touch the leading-wires to the two binding-posts after all connections are made. If the circuit is perfect, the needle will move along the scale. If the needle does not move, or not as far as it should, there is a break or some high resistance like a bad joint. Single electric blasting-caps can also be tested, both before and after loading them in the hole, simply by touching the end of the cap-wires to the two posts. It is excellent practice to test electric

blasting-caps and delay-electric igniters before and after loading. Wiring for electric blasts must be well and carefully done to insure success, the work of wiring may be divided into three parts, connecting the detonator-wires to the leading-wires and connecting the leading-

FIG. 1

wires to the blasting-machine. Connections between the detonator-wires must be well made; first scrape the bare ends of the wires with a knife-blade, and join them with a long hard twist, known as the Western Union twist (see Fig. 1). Never hook wires together as shown in

FIG. 2

Fig 2. In making connections between detonator-wires and leading-wires, the same precautions must be observed with regard to scraping the ends of the wires. Wrap the ends of the detonator-wire tightly around the end of the leading-wire about 2 in. from the end, as in Fig. 3. Then

FIG. 3

bend the end of the leading-wire back sharply and take a turn or two of the detonator-wire around the hook. Connecting the leading-wires to the blasting-machine is done by loosening the wing-nuts on the two binding-posts and inserting the end of the leading-wire into the small

FIG. 4

hole in the post and tightening the wing-nut on the wire.

When using a blasting-machine all circuits must be in series, as shown in Fig. 4. In wiring up a blast known as series-connections, one wire from each hole should be connected to one wire in the next hole, and so

FIG. 5

on to the end, when only the two end-wires are left free. These are connected to the end of the leading-wire. For electric blasting where lighting or power-circuits are

used the parallel-connections should be made as in Fig. 5. This type of connection cannot be used successfully with a blasting-machine. The parallel-connections differ materially from the series-connections and should not be confused with one another. In order to obtain satisfactory results the series must be used with the machine and the parallel with a power-circuit. A parallel-connection is made by connecting one wire from each hole with the leading-wire. In wiring a blasting-circuit all joints must be protected against short circuiting, especially in wet ground. This is done in several ways. When connections lie on moist ground or in water they must be held away by bending them on sticks or blocks, so that only the insulated part of the wire touches the ground or the supports; or the joint should be insulated with tape. All joints covered with water or dirt should be well insulated with good waterproof tape and made as near damp-proof as possible.

TUNGSTEN CONCENTRATE is usually pulverized and digested with acids for extraction of the metal. Any method of decomposing wolframite with acids for precipitating the tungstic acid should leave the manganese in solution, but in practice small amounts of the manganese will be carried down mechanically in the precipitate, and the quantity will be greater with an increase of the manganese-content in the original concentrate. In the treatment of scheelite the ore or concentrate is digested with boiling hydrochloric acid, to which small quantities of sodium or potassium chlorate are added as oxidizers. This method is also adapted to any ore of tungsten. The objection to it is that the silica remains with the tungstic acid, and either has to be left in it or removed by a separate process, such as leaching with ammonia in which the tungstic acid is soluble to the exclusion of the silica. If tungsten concentrate is first fused with alkalis the tungsten is converted into a soluble tungstate, such as sodium tungstate. After dissolving the salt from the fusion the tungstic acid may be precipitated by adding an acid, leaving the manganese in solution. Part of the silica would remain in the solution, but a part would be precipitated with the tungstic acid. According to R. B. Moore of the Bureau of Mines, the best way to convert tungstic acid into metallic tungsten is by heating it with powdered charcoal in a furnace at a bright red heat. This reaction can be obtained either in graphite crucibles or in cast-steel pots, or in steel-tubes.

ASSAYS for private parties are not made by the Bureau of Mines nor by other branches of the Government service free of charge, as this would interfere with professional chemists and assayers. The Bureau, however, furnishes lists of assayers and chemists on request. The Director of the Mint, on the other hand, announces that assays will be made for private parties at the mints situated in Philadelphia; New Orleans; Carson City, Nevada; Boise, Idaho; Helena, Montana; Seattle; and Salt Lake, as follows: determination of gold and silver, \$1; copper, tin, zinc, iron, lead, and tungsten, \$1 for each metal.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## CRIPPLE CREEK, COLORADO

**IMPORTANT DEVELOPMENT OF NEW VEINS IN THE CRESSON CONSOLIDATED MINE.—DIAMOND-DRILLING DISCOVERS NEW ORE-BODIES.—LESSEES CONTINUE TO OPERATE AT GOOD PROFIT.—DISASTROUS FIRE AT LAST DOLLAR.**

A new orebody of great richness is under development at the 1400-ft. level of the main shaft of the Cresson Consolidated Gold Mining & Milling Co., on Raven hill, according to A. E. Carlton, president of the company.

The dividend was paid July 10 at the regular monthly rate of 10c. per share and amounted to \$122,000.

During May new ore of the net value of \$19,572 was added to ore reserves, which June 1 were estimated to have a net value of \$3,817,000.

The 16th level has cut the contact and a drift has been turned north-east to cut the 1500-ft. level orebody partly developed by a winze from the 15th level. It will be necessary to drive about 600 ft. and the orebody should be reached about October 1. The main cross-cut has intersected a vein showing a 6-in. streak sampling \$20 to \$28. This did not show any value on the 15th level.

The diamond-drill has cut an orebody on the 14th level which averages \$35' over a width of 8 ft. A second hole 30 ft. away showed two feet of ore assaying over \$1500 per ton. This is ore which probably would not have been found in the ordinary course of development. A cross-cut is now being driven. A cross-cut from the Roosevelt tunnel to intersect the Cresson shaft is now under way.

The annual stockholders meeting has been called for September 4. The Golden Cycle M. & R. Co. paid its regular monthly dividend of 3c. per share, amounting to \$45,000, on July 10. A. E. Carlton is also president of the Golden Cycle company.

The directors of the Vindicator Consolidated Gold Mining Co. declared the regular quarterly dividend of 3c. per share last week, to be paid on July 25 and will amount to \$45,000.

The Granite Gold Mining Co. on July 5 paid 1c. per share, amounting to \$15,500. The company will pay regular monthly dividends and it is expected that the rate either will be increased or that the company will go on a monthly dividend basis.

A call has been issued for the annual stockholders meeting of the Camp Bird Mining, Leasing & Power Co., to be held at Pitkin, Colorado, on August 8, for the election of directors. This company holds a six years' lease on the property on the Rose Nicol G. M. Co., on Battle mountain, in this district, and sinking has been started from the 650-ft. level. The shaft will connect with a lateral from the Portland No. 2 shaft at the 1000-ft. level.

Sinking has been resumed by Edwin Gaylord in the Forest Queen shaft, on Ironclad hill. The shaft, now 650 ft. deep, is to be sunk to the 800-ft. point. The station at the 650-ft. level has been enlarged and an underground-hoist installed. Production from the upper levels will continue while sinking is in progress. California parties are part owners of this mine.

The Eclipse Leasing Co., holding a 5 years' lease on the Joe Dandy mine, to the Joe Dandy Mining Co., on Raven hill, has finished sinking and cutting of stations at the 600, 700, and 800-ft. levels, and is mining a good grade of ore in both the new 6th and 7th levels. Production has been resumed. The

Joe Dandy Mining Co.'s stock is not listed on Colorado exchanges.

A consolidation was effected last week, at meetings of stockholders of the Albert Beacon Gold Mining Co., the Cripple Creek General Mining & Exploitation Co., and the Gold Camp Syndicate, whereby the holdings of the companies in this district, comprising 57 acres patented on Bull, Ironclad, Newton, and Beacon hills, will be taken over and operated by the Victory Gold Mining Co., a Colorado corporation, to be incorporated this month. Harry J. Newton, of Denver, will be the president of the new company.

The July production of the mines of the United Gold Mines Co., operated under lease, totaled approximately 2500 tons of an average value of \$20 per ton—a gross production of \$50,000. The mines from which the ore was shipped were the Trail, on Bull hill, with 3 sets of lessees; W. P. H. mine, Ironclad hill, leased, and the Mohican, a fractional claim on Battle mountain, operated by the Granite Gold Mining Company.

The output from the main shaft of the Jerry Johnson Gold Mines Co., on Ironclad hill, operated by Frank Galey and son, and the Cripple Creek Deep Leasing Co., totaled 425 tons. The ore from the Galey lease averaged better than \$30 per ton, one car bringing settlement at \$47.80, and a second car \$57 per ton.

The El Paso Consolidated Gold Mining Co.'s lessees, 15 in number, mined and shipped 500 tons of \$20 ore during June. The company is not operating.

The mine-plant, shaft-house, ore-house, blacksmith-shop, powder-magazine, and equipment at the Last Dollar mine, on Bull hill, with contents were totally destroyed on July 7. The mine is under lease to the Catherine Gold Mining Co., Charles Walden, of Victor, general manager, and is owned by the Last Dollar Gold Mining Co. The fire was caused by lightning setting fire to the ore-house. The men were brought to the surface in safety, the engineer sticking to his post despite the fact that the magazine was enveloped by fire. The magazine caught fire from the flying embers and with its contents, 40 boxes of explosives, burned without explosion, except the caps. The Catherine company has recently installed a powerful electric hoisting-plant, and 12-drill electrically-driven compressor, at a cost exceeding \$15,000. The total loss is in excess of \$25,000. Mr. Walden leaves for Chicago this week to consult with Eastern directors of his company, and it is expected that when the insurance has been adjusted the plant will be replaced and operations resumed.

## TORONTO, ONTARIO

**THE THREATENED STRIKE OF MINERS AT PORCUPINE IS AVERTED BY THE MINE MANAGERS RAISING WAGES.—HOPE FOR SIMILAR ACTION AT COBALT.—THE CROWS NEST PASS COAL MINES TO BE OPERATED UNDER DIRECTION OF THE GOVERNMENT.**

All danger of a general strike in the Porcupine district has been averted by the course taken by the managers of several of the leading mines. While declining to recognize the union, on the ground of its affiliation with the Western Federation of Miners, they agreed to hold conferences with representatives of their own employees, with the result that in several cases the question of wages has been satisfactorily adjusted. The McIntyre and Dome Mines, and the Tough Oakes, at Kirkland

Lake, have granted an increase to mine and mill-workers of 50c. per day, to continue as long as the cost of living as shown by the Dominion Food Commission remains higher than in August 1914, all other bonuses being discontinued. The Hollinger Consolidated has granted a flat-rate of \$4 per day to all its underground workers, also discontinuing the 'loyal service' bonus. The mill-men are not affected by the change. Other companies have held conferences with their employees, the results of which have not been announced. One effect of the amicable settlement of the difficulty has been to attract to Porcupine many of the miners of Cobalt where the situation, though less menacing, is still uncertain. A strike vote taken on June 24 by the Cobalt miners was, by a large majority, in favor of a strike if their demands were not granted, but it has not been followed by any decisive action, as it is understood the matter has been referred to the union headquarters at Denver. In the meantime the settlement effected at Porcupine leads to the hope that similar action may be taken by the Cobalt mine-owners, as the local union leaders say that they will not press for the recognition of their organization provided the demands of the men as to wages are met. As the workers are now receiving bonuses based on the high price of silver, practically equivalent to the wage increase asked for, it is unlikely that a strike will result.

At the Dome Mines the cross-cut on the 700-ft. level is expected shortly to cut the large body of ore averaging \$17 per ton in gold, as indicated by diamond-drilling. It is anticipated that early in August the cross-cut will have penetrated the full width of the ore, 119 ft., and that stoping will have begun. The 4-weekly statement of the Hollinger Consolidated shows a continued decline in production. Gross profits for the period ended May 20 were \$92,809, as compared with \$194,688 for the previous 4 weeks, the tonnage treated being 35,337 tons of the average value of \$7.49 per ton, as compared with 42,849 tons of the average value of \$9.20. Working costs were \$4.66 per ton. The mill ran 65% of possible running time. The deficit was reduced to \$81,375. The central shaft is in operation and will be used exclusively for hoisting ore. A circular issued to the shareholders states that the directors have no intention of closing down the mine, but as long as unfavorable labor conditions continue may devote their attention mainly to development so as to get the mine in a position largely to increase the output when an adequate supply of efficient labor is to be had. The Schumacher has temporarily closed down both the mine and mill owing to labor shortage. At the McIntyre the main drift at the 1000-ft. level is over 1100 ft. long with a face of ore 52 ft. wide. The average grade throughout the mine has risen to \$12 per ton. The diamond-drill working on the 1000-ft. level has passed through a vein at the 1325-ft. level 22 ft. wide, which is stated to run \$20.50 per ton. New equipment is being installed preparatory to deeper sinking. At the Dome Extension diamond-drilling is in progress from a station at the 600-ft. level, 2000 ft. distant from the Dome glory-hole, and preparations are being made to sink an incline to 1600 feet.

The La Rose Consolidated is developing the Violet property to the east of the O'Brien and will sink to the 300-ft. level to prospect the veins coming in from that direction. The Adanac is opening up a 4-in. vein on the 312-ft. level, which in places assays 1000 oz. per ton. The Mining Corporation of Canada, now operating the Little Nipissing, has encountered, in a winze put down from the 200-ft. level, a 4-in. vein carrying native silver at a depth of 50 ft. At the Peterson Lake a 3-in. vein carrying high-grade ore, and believed to be a continuation of Nipissing vein No. 10, has been found and is being opened up.

The protracted strike of coal miners in the Crows Nest Pass district and the adjacent parts of Alberta and British Columbia, where 6000 men have been idle for several months, has been terminated by the action of the Government under the

War Measures Act. W. H. Armstrong, of Vancouver, has been appointed commissioner with power to operate the mines, or to compel the owners to do so. He has ordered the mines to be re-opened at once, the men to receive an advance of 22½% over former wages; a commission to investigate the cost of living to be appointed every four months if requested by either party. This action was taken owing to the failure of negotiations which had resulted in a tentative agreement as to wages, but which were discontinued because the mine-owners insisted on a clause penalizing the men should they quit work. This provision will be eliminated. As the men have been widely scattered during the strike, it was not expected that work could be resumed before July 3. The mines will be worked day and night to secure as large an output as possible. As the coke supply of the smelters at Grand Forks and Trail, B. C., is dependant upon the Crows Nest Pass coal mines, the resumption of operations at the collieries is a matter of great importance to the metallurgical industries of British Columbia.

### JUNEAU, ALASKA

THE READY BULLION, ALASKA GASTINEAU, AND ALASKA JUNEAU MINES ALL RUNNING AT REDUCED CAPACITY OWING TO SHORTAGE OF LABOR.—A FINNISH MINER'S IDEA OF A CONTRACT.

The shortage of labor in the Juneau district is fast becoming a serious matter. The Ready Bullion mill on Douglas island has been reduced to day-shift operation only, to allow all the available men to be sent underground, in an effort to rush development work on the 2400 and 2600-ft. levels and also to complete the filling of the old stopes with waste rock, which is being mined from the foot-wall on the 450-ft. level. This filling of old stopes will avert all possibility of a disaster in the Ready Bullion mine similar to that which occurred at the Treadwell mine.

The Alaska Gastineau Gold Mining Co. is finding it difficult to keep up the tonnage of the mine, owing to the shortage of men. The mine is running with approximately 100 men short. The Alaska Juneau is suffering similarly, though not to the same extent, as their daily output at present is averaging but 2000 tons.

W. S. Pecovitch, superintendent of the Funter Bay mines, at Funter Bay on Admiralty island, recently returned from the East to Juneau. He has made financial arrangements to develop the property and will leave for the mine as soon as possible with 15 men to commence work. The present plans include the driving of a cross-cut adit to cut the 18 veins which outcrop on the surface. The result of this cross-cut will determine the future course to be pursued in equipping and developing the property.

Very seldom is a humorous occurrence reported as happening in the operation of a mine. There are good stories of salting samples during an examination, and shrewd bits of financial finesse in mining deals, but for a clever slip-over, the following has few equals:

In one of the big mines of the district, recently, a Finlander had a contract to drive three raises from various points to the surface. The work was started late last fall and two raises were completed during the winter. The last raise being 100 ft. or so, longer than the others, took longer to drive. The rock was hard, and as the raise neared the surface, the flow of water increased until the stream in the raise was like a small waterfall—cold water too. The raise was driven from an adit, to reach which from the mine, a pack of perhaps 200 yd. was necessary. And the trail was through deep snow, generally fresh fallen every day. Labor was almost impossible to get, and to send a man to that raise, was equivalent to giving him a time-check. The Finn even put in some shifts himself, packing steel, drilling, packing powder, and blasting, alone.

One morning the contractor met the foreman and announced that "she was in—snow on the bulkhead." The measurement on the previous day showed the raise up 253 ft., which was about 10 ft. short of the calculated length, but that was accounted for by the fact that there could easily have been 6 or 8 ft. of dirt on bedrock at the surface. The foreman went up the raise, found snow on the bulkhead, and took no trouble to go to the face, which would, he judged, be loose and dangerous. The raise was reported as finished and the contractor was paid in full for the work.

Two months passed, and on the surface, no hole appeared in the 15 ft. of snow that covered the raise. This was considered so strange that the raise was investigated and the face was found to be in solid rock, with not a sign of daylight. That Flinn had packed that snow up the raise. After one trip up the raise to the top, the foreman concluded that the contractor wasn't so crazy after all.

The Alaska Treadwell Gold Mining Co. has men at work on the Red Diamond claims, on which a working option was recently taken. This development work is in charge of Monte Benson, recently a foreman of the Alaska Mexican mine.

Junk dealers from Seattle are making a clean-up in the district, made possible by the high price of scrap-iron. The abandoned equipment of the old Nowell Red mill, in Silver Bow basin, and of the old Alaska Juneau 30-stamp mill, and of the old mills in Sheep Creek basin, has brought a price averaging \$12.50 per ton, on the ground.

The Pacific Coast Gypsum Co.'s property at Gypsum, on Admiralty Island, is making regular shipments of 3000 tons per month to Tacoma. There are 25 men working at the property. Mining is in progress on the 190-ft. level, and the 300-ft. level is being developed. D. C. Stappleton is superintendent.

At William Henry bay, on the west shore of Lynn canal, E. Aldrich is developing a copper prospect. He is working seven men, establishing a camp and installing machinery, preparatory to development.

J. E. Berg, superintendent of the Pueblo mines, at White Horse, Y. T., has returned there to re-open the mines, which were recently shut-down by order of the Canadian authorities, following a serious cave at the mine, in which seven men were killed.

### TREADWELL, ALASKA

THE READY BULLION MINE AND MILL AGAIN IN OPERATION.—A SHORTAGE OF LABOR RESTRICTS OPERATIONS.—COAL OUTPUT OF ALASKA INCREASING.—MINERAL PRODUCTION.

Owing to the scarcity of men to work in the mine, the Ready Bullion mill is now being operated during the day shift only, in order that more men can be put in the mine to prepare for increasing the output which insures both continued and increased operation of that property. The shortage of labor is still being felt on the island, although several men have signed on recently. It is believed, however, that more men will be available in a few weeks.

The Treadwell company has consummated the sale of the building and structural steel of the Central crushing plant. The work of dismantling started during the week. The six crushers will be stored for the present. Development work on the Diamond group will be started by the Treadwell company during the coming week.

Two mines in the Matanuska coal district, into which the United States railroad is being constructed, are producing coal for the market. The mine of William Martin on Eskra creek is employing 50 men, and up to May 29 had shipped 3000 tons of coal to Anchorage. The daily production is about 40 tons. The mine of the Doherty Coal Company, at Moose Creek, has sold 12,100 tons of coal to the Alaskan Engineering Commission since last August besides a considerable amount

to the residents of Anchorage. Fifty men are employed at the Doherty mine. Other properties are being opened. All these coal areas are leased from the Federal government. A statement of the value of the exports from Alaska for the six months ended June 30, 1917, has been prepared by the collector of customs, J. F. Pugh. The following are the value of mineral exports: copper ore, \$15,007,211; gypsum, \$29,600; lead ore, \$54,316; marble, \$28,252; gold and silver, \$4,136,831.

### YERINGTON, NEVADA

THREE DIFFERENT COPPER-LEACHING PLANTS IN OPERATION.—

EMPIRE NEVADA.—THE KENNEDY CONSOLIDATED SALE.—

MONTANA YERINGTON.—SUCCESSFUL COPPER LEACHING.—THE ROCKLAND MINE HAS NEW EQUIPMENT AND MAKING GOOD RECOVERY.

There are two copper-leaching plants working in the district and a third is being built on the property of the Empire Nevada Copper Company.

The first plant was built at the Thompson smelter a few years ago and the Weidline process adopted. This is not a commercial plant, having been built for experimental purposes only. Leaching is done with sulphuric acid, and the copper-bearing solution is then brought to digester-tanks under pressure in the presence of steam. Native copper is precipitated and the sulphuric acid regenerated. The troubles have been mostly mechanical and are being gradually overcome. It is understood that the process is a success from a metallurgical standpoint.

The Nevada Douglas Con. Copper Co. has spent a large amount of money experimenting and has the only commercial plant in the district. The daily capacity is 150 tons at present. Crushing is done dry and the ore is leached with sulphuric acid, and the copper is precipitated on scrap-iron. The sulphide ores are first roasted in a Wedge furnace.

The Walker River Copper Co., of which J. H. Banks of New York is consulting engineer, is building a 20-ton plant at the Empire Nevada mine. The ore is crushed dry and leaching takes place in tanks. The mill equipment is all of Dorr make. Ferric chloride is used for dissolving the copper, which is precipitated on scrap-iron, and the ferric chloride regenerated by electrolysis. The flow-sheet was worked out after several years of laboratory experimentation. If the present plant shows the success anticipated, a large plant will be built. The Empire Nevada is considered by many engineers to be the largest property in the district. Churn-drilling has disclosed several million tons of oxidized ore averaging about 2% copper. J. E. Gelder is the local manager of both the Walker River Copper Co. and the Empire Nevada holdings.

The old Kennedy Consolidated property, at Buckskin, has been sold to J. F. Cowan and associates of Salt Lake City. This property is considered to be valuable but former operators were unable to work it during the years when copper was below 20c. per lb. The mine makes considerable water. The orebody is about 30 ft. wide and of undetermined length. The ore is a heavy sulphide mixture of barren iron pyrite and chalcopyrite averaging about 2% copper and containing considerable gold. It is reported that flotation experiments have been successful.

The Montana Yerington is under option to J. H. Brady, of Tonopah. P. Ober is in charge and a few men are employed in development work. This and several other properties of the district would be shipping ore to the Thompson smelter but for the fact that the Mason Valley Mines Co. will not receive any custom ore. The opening of the smelter has not been of any benefit to the small shipper and several anticipated sales have not materialized because the prospective purchasers could not market their ores. The general run of ore in the district will not average over 3 or 4% copper and shipment to

Salt Lake City smelters at a profit is therefore not possible. At the present time the smelter is treating about 800 tons of ore per day. This comes from the Bluestone mine and the Mason Valley. Occasional small shipments of high-grade from Ludwig are also treated as this ore has very desirable fluxing qualities. The capacity of the smelter is about 1800 tons daily, but there has been such a serious shortage of coke that running at capacity has been impossible.

This, however, is not the reason why custom ore is refused. The general opinion in the district is that the contract between the smelter and the Bluestone mine, owned by Capt. Delamar, stipulates that Bluestone ore up to 1400 tons per day must be accepted first, and that leaves little chance for ores from other properties.

The only gold mine in the district, which is located in Mineral county south of Yerington, is the Rockland mine that has been operated by the Pittsburg-Dolores Mining Co. for several years. Recently this company has installed an electric hoist wherewith to explore the main fissure at depth. It is understood that the lowest workings show ore of good grade and that the shoots are more persistent than was the case in the old workings. For the past two years the ore has averaged about \$9 and has largely come from the upper zones. A complete cyanide-plant is operated, and extraction is around 90%. The ore is difficult of treatment. E. J. Schrader is manager of the property.

### LEADVILLE, COLORADO

THE MINERS OF THE DISTRICT, AFTER AN ANGRY SESSION, DECIDE TO STRIKE.—THE MINE OPERATORS REMAIN INFLEXIBLE AND ARE DETERMINED TO WORK THE MINES AS WELL AS THEY CAN WITH THE AVAILABLE CREWS.

The strike which was to have been called in the mines of the Leadville district on Saturday morning, July 14, has been postponed until Saturday July 21, pending the outcome of a conference, which Chas. H. Moyer, president of the International Union of Mine, Mill, and Smelter Workers, and John R. Lawson, a noted Colorado labor worker, are to hold with Secretary of Labor Wilson, at Washington. The decision to postpone the strike was reached Friday night, July 13, when both Moyer and Lawson addressed a closed meeting of the union men from 9 o'clock until past midnight. The proceedings of the meeting were not made public with the exception of the statement announcing that the strike had been postponed for one week.

The efforts of Verner Z. Reed and George W. Musser, federal mediators appointed by Secretary Wilson to arbitrate between the Leadville union and the operators, failed to bring about a compromise. Following these conferences between the committees from both sides and the mediators which were held at the home of Mr. Reed in Denver, it was announced that Moyer and Lawson would come to Leadville to address the union. Their mission was unknown but it is believed that Mr. Reed brought Government influence to bear on the situation, which asked that the International heads persuade the local union to postpone the strike. Their success in this is reported to have come only after a bitter debate among the union men, and it is stated that many of the foreign-born members of the union left the meeting after the vote for postponement had carried and tore up their membership cards.

The strike question is not entirely settled, but there are many more possibilities for averting it than appeared a week ago. The result of the conferences at Washington will have a great influence on the future action of the union.

The operators have not made any public statements regarding the situation although many of them have declared their willingness to settle the labor-union question in the district once and for all time, while the matter is in the air. They are determined upon ignoring the union and have taken steps to

protect their properties, prepared to continue operations with such force of men as they can secure. From 200 to 300 members of the State militia are on guard duty in the district. On the other hand, it is generally believed that should the efforts of the union to call a strike fail entirely, the operators will increase wages 50c. per shift. Such an action is eagerly looked forward to by the citizens generally, as it is believed it would go a long way toward ending labor troubles in the district for many years.

The mines are all working as usual but with decreased forces in many cases. Several hundred men, anticipating the strike call, left the district last week.

A canvas of the district shows that there are 49 properties producing ore with an output ranging from 100 tons to 10,000 tons per month. The combined output during the month of June was 63,300 tons. There are 1830 men employed in the mines of the district. At the two smelters, the Arkansas Valley plant of the A. S. & R. Co., and the Western Zinc Oxide plant, 900 men are employed and a combined total of 26,500 tons of ore is treated each month.

C. J. Dold, manager for the Dold Mining Co., is going ahead with operations at the Northern shaft near the head of East Ninth street, regardless of the pending strike. Sinking has been undertaken with two shifts, while another force of men is cleaning out the old drift leading to the Newell shaft, where it is planned to install a hoisting plant.

The Northern shaft was 640 ft. deep before sinking was started, the bottom being in the gray porphyry, which is estimated to be about 50 ft. thick. Underlying this formation, the second contact, in the blue lime, will be encountered. This second contact, which has been extensively developed in the Penrose and Coronado properties—the latter adjoining the Northern on the south—was the most productive area of the Down Town section. Huge bodies of iron, manganese, lead carbonate, silver chlorides, and zinc carbonate were uncovered in these properties. Their extension into the Northern ground is taken as assured by mining authorities here who predict that the Dold Mining Co. will develop one of the richest mines in the district.

The miners affiliated with the union struck according to programme on the morning of July 21, by which 37 mines were affected. At each of the mines 8 or 10 men were allowed to remain for the purpose of operating pumping machinery to keep the mine workings free from water.

### SUTTER CREEK, CALIFORNIA

BONANZA ORE IN THE LOWER LEVELS OF THE CENTRAL EUREKA MINE REPORTED.—RESULT OF UNFAILING EFFORT TO PROVE THE MINE AT GREAT DEPTH.—DEVELOPMENT AT THE SOUTH KEYSTONE.

After several years of unsatisfactory development, but unremitting effort, the management of the Central Eureka mine has found what promises to be a shoot of bonanza ore on the 3350-ft. level, where pay ore was found in both the north and south faces of drifts run from the shaft. It is reported that the average value of the ore is about \$11 per ton, which, if true, means substantial dividends for the fortunate shareholders, for the Central paid dividends on \$6 ore some years ago. In addition to this new and gratifying discovery on the 3350, good ore has been found and is being developed on the 3425-ft. level.

These discoveries will illustrate the need for courage as well as financial ability in persistently sinking and exploring the veins of the Mother Lode in Amador county.

At the South Keystone development is proceeding from the North Star shaft, where a level is being driven north into the South Keystone mine, the object being to reach a body of rich ore at a depth of 600 ft. Some of this ore was high-grade when it was worked many years ago.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—Monte Benson with 12 men left Treadwell on June 6 for the west side of Douglas island, where a drift will be run on the Red Diamond mining property, on which the Treadwell company has secured an option. Later it is expected a tunnel will be driven through the range separating Treadwell from the Red Diamond property, so that ore may be treated at the Treadwell mills. F. W. Ketchmark, of Windham Bay, has struck a good body of ore on his property near the mouth of Spruce creek.

According to advices received in Juneau, troops from Fort Lisicum have gone to Kennecott to remain during the strike of the copper miners at that place. While no trouble has occurred and none is anticipated, it was thought wise to have troops there. The striking miners are quietly encamped at Blackburn with their camp gaily decorated with American flags and bunting, and they are maintaining good order, administering the affairs of the camp themselves. Now that the superintendent is back at the mine, it is expected that the trouble will be adjusted. The men who were in charge during his absence were unable to handle the situation for lack of authority.

R. G. Wayland, Peter Johnson, and Thos. McDonald, are preparing to leave for the Atlin district on the next trip of the 'Mariposa.' The party will be gone a month or more and will examine and report on mining properties in that district. Within a few days the Treadwell company will have cars running for the accommodation of the workmen going and coming from the Ready Bullion mine.

Treadwell, July 8.

The Alaska United Gold Mining Co. reports returns for May as follows: Ready Bullion mill ran 30 days 7 hr. 15 min.; by water power, 24 days 2 hr. 39 min.; by electric power, 6 days 4 hr. 36 min. Crushed 24,346 tons, concentrate saved 669.74 tons. (700-mill 44.7 tons.) No free gold saved. Value of Ready Bullion concentrate, \$44,862.10; of 700 concentrate, \$4918.50. Total realizable value, \$49,282.80. Operating expense, \$44,711.24. Construction expense, \$5380.28. Estimated net returns Ready Bullion, \$4193.13 loss. 700-mill, \$1187.15 profit. Other income, \$2681.88. Yield per ton of ore \$1.84.

## ARIZONA

At the great copper mines in the districts of Warren, Globe, and Miami, the members of the I. W. W. fraternity are being warned to keep away—they are not wanted nor needed as men from other districts and other States are coming in, and the management of the various mines have decided to take on only American miners hereafter. At the Copper Queen it is said that the working crew has been recruited to about 75% of the usual number. Every man inquiring for work is closely questioned before being accepted, if he is taken on at all. It is thought at Bisbee that the trouble is at an end, but at Globe there is still some dissatisfaction among the men, who complain that they were misled by the union officials. In the Globe district the Miami wage-scale has been adopted. A general increase of 10c. per shift was made to conform to the Miami sliding scale, which is based on the price of copper. Wages are now \$5.50 per shift, the highest ever paid in the Globe-Miami district.

Press dispatches dated July 19, at Globe, state that two German miners were arrested at Miami, at the instigation of

the Federal Department of Justice, and that a search of their room was made resulting in the discovery of shotguns and revolvers with ammunition. One of them carried a certificate of registration with a German consul as a German reserve officer.

## MOHAVE COUNTY

(Special Correspondence.)—All labor difficulties have been adjusted by committees of mine operators and the International Union of Mine, Mill, and Smelter Workers. The operators raised wages and the union is working with the operators to keep the turbulent labor-element out of the union and consequently out of employment here. All mines here have resumed with a full force.

The Minnesota-Connor is sending 200 tons of dump-ore to the new Steffy custom-mill. The old workings have been unwatered.

The Payroll is shipping ore from the 200-ft. level to the custom mill. Stopes are being opened on the 200-ft. level.

The Schenectady has closed down until machinery parts arrive. A fire destroyed the shaft-house and slightly injured the machinery. Work will be resumed soon.

The Steffy custom-mill expects to be running on custom ore by July 20. Its capacity is 300 tons daily.

The Copper Age mill is being tested out and will be placed in operation in a few days.

The New Tennessee has a good ore-shoot, which has been continuous to the present bottom of shaft, at 235 ft. from the surface. The vein is from 4 to 5 ft. wide and runs well in gold and lead.

At the Schuylkill the pumps have been lowered to the 800-ft. level, a new boiler has been installed, and water can now be handled from the lower levels.

The Bullion mine, Jesse Knight's property, is going ahead with three shifts. The electrically driven hoisting-machinery and compressor are working smoothly.

The New Mohawk soon will begin cross-cutting from the bottom of No. 2 shaft. A new shaft is soon to be started near the intersection of the Silver Key vein with the Juno vein.

Chloride, July 16.

(Special Correspondence.)—The advantage of maintaining harmonious relations between the mine-owner and the miner has been shown during the recent revolutionary campaign of the I. W. W.'s in Arizona. Oatman was protected from the I. W. W.'s not by troops, peace officers, or citizens' committees, but by the miners. When the first advance guard of agitators appeared here they were met and told not to attempt to start any trouble. The men who told them this were working miners who represented the majority of the men working in the mines and mills. The leaders departed and have not been seen at Oatman since. This incident is typical of the conditions that prevail in this district. Nearly all the working miners are stockholders in Oatman companies, or are owners of mining property here, and therefore understand the difficulties of the mine managers. The operators recently granted an increase of 50c. per day in pay. In order to revive some of the companies that have been insufficiently financed, a movement is under way to change them to assessable corporations. Nearly all Arizona mining corporations are in the non-assessable class, but many of the stockholders and officers begin to doubt the wisdom of this.

Three Oatman companies have financed new development by means of assessments. One of these is the Vivian Mining Co.,

owner of the Leland and Vivian properties near Oatman.

Another company that has adopted the assessment method is the Gold Range, which has changed its charter and has levied an assessment on all stock.

Motor-trucks will be used to transport ore from the Aztec shaft of the Tom Reed Gold Mines Co. to the mill, as the Government has conscripted the entire output of the A. Leschen company that had contracted to deliver a cable to the company. Two additional trucks have been put on to supply the mill with 300 tons per day.

Oatman, July 16.

#### PINAL COUNTY

The management of the Inspiration Copper Co. has paid off employees, both the faithful and the strikers, and closed-down its plant. The mine does not have to be unwatered, owing to its natural drainage, and this makes it possible to shut-down at a moment's notice and reopen quickly.

The mill had reached capacity operations a short time before the miners went on strike July 2, in the treatment of more than 20,000 tons of ore per day. Upon resumption of operations it will take some time before it can again be brought up to the same level of production.

#### YUMA COUNTY

(Special Correspondence.)—At the Swansea mine two strikes have occurred in the last 30 days. The first was for a raise to \$5.40 per day, which was granted. At the time of the first strike when men were given the order to appear on top, the majority of them did not know what it was about. The second walk-out was on account of the boarding-house. The superintendent, Mr. Lane, discharged them all, as he considered their alleged grievance trivial and not justified. This affected 120 men. Recently the W. A. Clark interests took over the Swansea mine on a 10-year lease. This called for a three-compartment shaft 1000 ft. deep and a 50% royalty on ores, which was not to be under \$5,000,000 in the 10 years. This property is owned by French and Belgium interests, only a small part of the stock being held in the United States. A great deal of stock was sold and the money was spent on the Clara Consolidated properties, of which the Swansea was one. The property became involved in debt and a receiver was appointed who placed Mr. Lane in charge. He paid about 60% of the debt while it was under his management. In the last year he has shipped to Humboldt from three to five cars of ore daily and occasionally some to Sasco. When the debt has been paid, the property will be turned back to the old stockholders.

All of the ore shipped lately has been taken from No. 2 and No. 5 shafts. The ore averages 3% in copper. It occurs with specular iron in the form of a sulphide. The ore is desirable at the Humboldt smelter on account of its fluxing properties. It is reported that the old smelter at Swansea will be moved to the Bill Williams river, and also that Clark has bought the Swansea railroad, running from Bouse to Swansea.

Mr. Wolacott, one of the lessees on the Bullard property, says they will soon have the drills running that were recently installed.

Wenden, July 18.

### CALIFORNIA

The magnesite producers of the Pacific Coast organized an association at the Palace hotel, at San Francisco, July 17, the purpose of which was to take steps toward securing congressional action to place a duty on imported magnesite. The organization will be known as the Western Magnesite Association. R. Adams, of Porterville, California, is president, F. S. White, of the Tulare Mining Co., is first vice-president, F. S. Sweasey, of White Rock mine, Napa county, is second vice-president, and A. N. Sears is secretary.

Reports filed with the State Mining Bureau for the week ended June 23 show 12 new wells started, making a total of 540 since the first of the year; 25 wells were reported ready for test of water shut-off; 14 deepening or re-drilling, and 3 abandoned.

#### FRESNO COUNTY

(Special Correspondence.)—The property of the Fresno Magnesite Co., near Piedra station, which was formerly owned by M. F. Tarpey, has been sold to the International Magnesite Co. of Los Angeles. A plant, consisting of crushing machinery and a rotary-kiln, will be purchased, and the property worked to capacity.

Fresno, July 18.

#### NAPA COUNTY

(Special Correspondence.)—The Socrates quicksilver mine has been examined by H. W. Turner in the interest of Honolulu capitalists who will follow the recommendations of Mr. Turner as to equipment, development, and operation of the mine.

The Etna quicksilver mine is now under the management of E. De Golia. E. B. Frost is superintendent, and recently took charge of the property.

Calistoga, July 18.

#### NEVADA COUNTY

(Special Correspondence.)—The Golden Center Mining Co. will spend \$200,000 for new development and additional equipment. The 1000-ft. shaft will be sunk to 2000 ft. and an extensive system of cross-cuts and drifts run. Because of the high price of materials, and the difficulty in securing good miners, it has been decided temporarily to discontinue all mine and mill production.

John P. Clark, of Truckee, has practically closed a deal with Salt Lake men for the sale of his High Grade property, in Meadow Lake district, where 25 men are employed and shipments of copper-silver-gold ore are being made. The Utah company is reported also to be negotiating for the Great Eastern property.

An examination of the Bitner copper mine, at Spenceville, has been made by J. C. Campbell, of Nevada City, for San Francisco capitalists. The Bitner contains large bodies of low-grade ore.

Hydraulic mining will be resumed at the Omega mine, three miles north-east of North Bloomfield. More pipes have been added and the restraining dams have been re-inforced. There is a large yardage of gravel and sufficient water is available to insure a long period of activity.

Grass Valley, July 17.

The Hoff-Price Co., of San Francisco, is developing an occurrence of chrysotile asbestos on the Yuba river a mile above Washington. The asbestos occurs scattered in veinlets through a large mass of serpentine. The veinlets are from  $\frac{1}{2}$  to 1 in. or more wide and the mineral appears to be of fine quality. Machinery will be placed on the property to prepare the asbestos for market.

#### SHASTA COUNTY

(Special Correspondence.)—L. Gardella, the Oroville dredge operator, is assembling material on Clear creek, three miles south of Redding, for the construction of dredge No. 2. Three of seven cars of lumber have arrived at the site and most of the machinery is on the ground.

The Accident Gold Mining Co. of French Gulch has made application for voluntary dissolution. Its properties and other claims in the neighborhood were recently taken over by the Shasta Hills Mining Co. Ed Hillman is superintendent.

The electrolytic zinc-plant of the Mammoth smelter, at Kennett, is working successfully and turning out a satisfactory amount of the metal. The structural difficulties encountered at the start have been overcome in the main.

Redding, July 14.

## TUOLUMNE COUNTY

H. Huston and associates are about to reopen the Keltz mine, situated 10 miles north of Soulsbyville, on the north slope of Elizabeth mountain overlooking the canyon of the South Fork of the Stanislaus river. The mine was operated for years by the late William Sharwood. It is equipped with a 10-stamp mill and the necessary buildings. All the work has been done through adits.

## COLORADO

## BOULDER COUNTY

(Special Correspondence.)—Encouraged by the increased price of tungsten, and the subsidence of the surface water, many lessees have resumed work. The prevailing idea is that the market is advancing. The result is that considerable ore is being held for better prices. The Long Chance Mining Co. has finished sinking in the Tungsten shaft. This makes the second 100-ft. lift made at this shaft in the last nine months, and gives them a depth of 300 ft. As soon as the ore-pocket and pump-station are cut, driving will start. This is now the deepest shaft in the Beaver Creek district. From indications it is believed that their next lift will pass through the schist. Prospecting on the 200-ft. level disclosed two new ore-shoots, which from the 1200 tons of ore already milled will exceed in value the rich surface deposits.

Nederland, July 11.

## BOULDER COUNTY

(Special Correspondence.)—The Illini Mines Co. has been organized. It is composed of Boulder and Denver men. James Ashmore, Andrew Whitehead, and Edwin K. Whitehead, of Denver, C. S. Sicklestear and Thos. S. Bailey, of Boulder, compose the directory. The company will operate on Wood mountain, at Wall Street. The Wood mountain mines have been big producers, and have large orebodies of good value. The group consists of 60 acres of proved mineral ground.

W. G. Spaulding, of Ward, this week shipped a car of high-grade gold ore, carrying a small amount of silver. The ore came from the Sullivan No. 2. John T. Bottom, a Denver attorney and owner of the St. Louis mine at Caribou, has been looking at his property.

The Boulder Tungsten Production Co. has begun operations in the big mill at the mouth of Boulder canyon. The acid-mill is about completed. This plant is said to be one of the largest in the United States. Jack Clark of the Boulder Production Co. says the tungsten outlook is first-class and he looks for a further advance in price. Feberite (Eagle Rock) is a thriving mining camp. Two mills are running on the ores of that district. The Black Prince mine has a vein from 1 to 2 ft. wide and has been supplying ore to the mill all winter.

W. A. Keeler & Son have a good lease on the Duncan property, which has been a good paying mine in the past. Bud Conger and Gordon Taylor have a paying property.

Broughton, Holmes, Shiply, and Hewitt are making regular shipments from the Wheelman property. Bow and Casten are taking out good ore from the Dora mine. A shipment of two lots of ore from the Brandenburg properties, on Left Hand, is attracting attention. It has a big, rich, and continuous ore-body. It is predicted a new mining town will spring up in this district.

Phil Worchester of the Colorado State Geological Survey, who has examined the molybdenum veins in Allen's Park, says not enough work has been done to determine the amount or quality of the ore, though several properties there have good indications and should be developed.

Eldora, July 12.

## IDAHO

## IDAHO COUNTY

(Special Correspondence.)—After sending a large quantity of ore from the Black Pine mine near Elk City, to the Washoe

smelter, at Helena, Montana, it was found that the ore was amenable to flotation and J. Reibcon, president of the company, has purchased all the machinery and equipment necessary for installation of a flotation plant with the expectation of having it in operation by August 15. Machine-drills are in operation and ore-bins are full.

Molybdenite and uranium ores have been discovered in the Knob Hill gold mine, owned by Frank Peck, in the Oro Grande district. More than 100,000 ft. of lumber will be used in the construction of the 300-ton mill, in course of construction, and in building the flume.

Elk City, July 16.

## SHOSHONE COUNTY

(Special Correspondence.)—D. W. Peoples recently obtained a 10-year lease on the dumps of the upper workings of the Bunker Hill mine up Milo gulch, above Wardner. In the gulch, at the base of the dump, he has constructed a concentrating-plant of 200 tons capacity each 24 hours. The mill has two Blake crushers, 5 jigs, 3 Deister tables, and a Standard ball-mill, from the Colorado Iron Works Co. of Denver, Colorado. The intention of Mr. Peoples is to add flotation-cells. The value in this dump, which covers 10 acres, is about one-third ounce of silver to a unit of lead. The rock of the dump averages about 3 to 5% lead. The dump came from miles of workings made in the '80s. Through lack of facilities at that time it could not be handled. The mill is run by electric power obtained from the Washington Water & Power Co., of Spokane.

Wardner, July 14.

## MONTANA

## BROADWATER COUNTY

(Special Correspondence.)—The Iron Mask mining claim, near Hassel, is being unwatered. The shaft is 350 ft. deep. No work has been done at the property for some time. The ore consisting of lead and zinc was formerly not profitable to mine, but with modern improvements in concentration it is believed it will pay well.

In Iron Age gulch, at Winston, two cars of silver-lead ore from the 300-ft. level is shipped weekly to the East Helena smelter.

James H. Smith is opening the Indian creek placer near the old towns of Hogen and Florence. He is putting in a bed-rock flume and is sluicing some surface ground near by. The gravel at the head of the old flume was found to be 6 to 7 ft. deeper at the upper end than at the lower, which necessitated the deepening of the bedrock drain. The work is almost completed and the giant will be turned on a 50-ft. gravel bank.

Winston, July 16.

## GRANITE COUNTY

(Special Correspondence.)—The Brooklyn Mines Co.'s property in the Philipsburg mining district,  $7\frac{1}{2}$  miles from the railway station of Maxville, consists of 10 claims. The principal development is a 700-ft. adit and much over-head stoping. The ore contains lead, silver, copper, and zinc, the greater part being in lead and silver, although the high-grade ore has run 300 oz. silver and 17% copper per ton. Electrical power is provided by the Washington Water & Power Co. of Spokane, Washington. Two shifts get out 75 tons per day, which is treated at the concentration-plant at the mine, to which lately has been added three Wilfley tables, making six in all, and six more flotation-cells. The concentrate is shipped to the Washoe smelter, at East Helena, H. Whitworth, of Drummond, is president of the company.

Drummond, July 16.

## SILVERBOW COUNTY

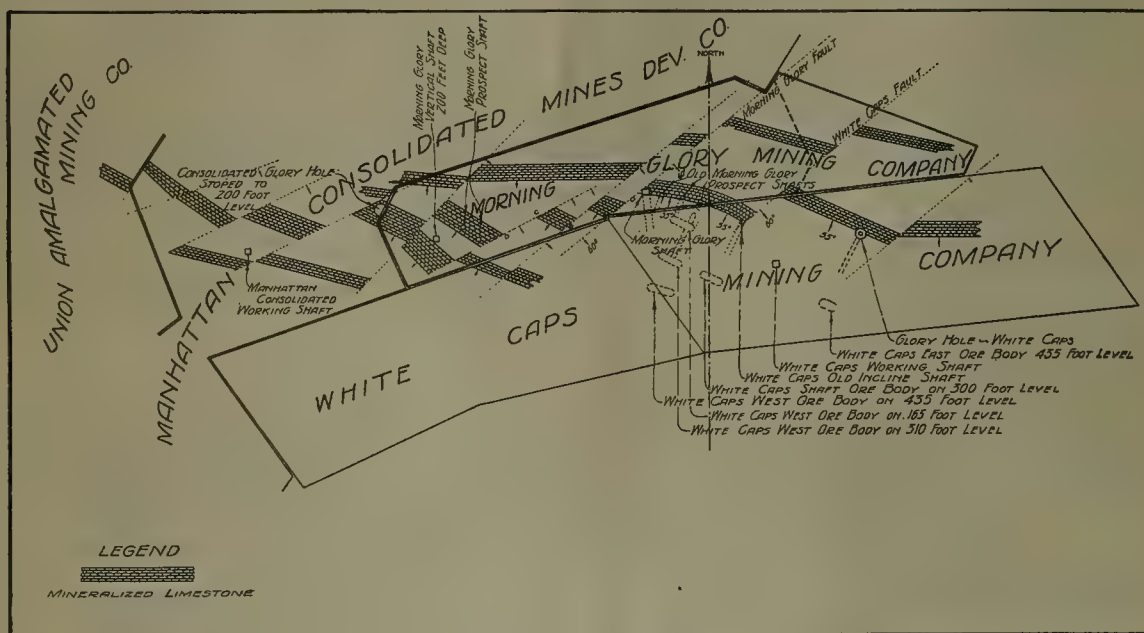

(Special Correspondence.)—The country rock of the Summit Valley mining district, east of Butte, at base of the Continental Divide, is the Butte granite. There are two distinct systems

of fracture—the east-west forms fissure veins, and contains the ore deposits. The vein-filling consists of iron pyrite, quartz, and copper sulphide, both chalcocite and bornite. The property of the Butte Czar Copper Co. is situated in this district and its development may mean much to the future of Butte. Two east-west fissure veins course through this property. The main vein is 40 ft. wide, with an apex of 1477 ft. This vein has been opened by a 300-ft. adit cross-cutting it 100 ft. below the surface. An 80-ft. drift on the hanging wall and one of 30 ft. on the foot-wall show continuous orebodies. Following the hanging wall is 4 ft. of sulphide ore containing 1 to 6% copper, and 2 ft. of the same class of ore on the foot-wall. The remainder of the vein is crushed granite over 30 ft. wide, with veinlets of quartz, iron, and copper. The machinery

The east drift on the 300-level cut the fault east of the lime, which contains the east orebody. The mine ore-bin will now be filled and the crushers, rolls, and conveyor-belts will be tried out. The mill construction is nearly at an end. An additional cooling-hearth has been built under the heating-hearths of the roaster.

Good progress in shaft-sinking has been made at the White Caps Extension. The three-compartment vertical shaft, each compartment being 4 by 4½ ft. in the clear, was sunk from the surface 22 ft. in the first 24 hours, three shifts being employed, using jackhammer-drills and sinking in soft shale. The shaft has reached a depth of 28 feet.

At the Manhattan Consolidated mines the east orebody, being developed from the third level of the Consolidated work-

MAP SHOWING THE COMPLICATED SYSTEM OF BLOCK-FAULTING AT MANHATTAN

furnishes power for hoisting, for running a compressor, and the pumps when necessary. A two-compartment shaft is to be sunk 300 ft. A leaching-plant will be built to save the copper in the water coming from the 40-ft. vein. The company is well financed, with C. F. Murphy, superintendent of the Butte, Anaconda & Pacific Railway, as president. Development is under the supervision of E. C. Meiklejohn and R. M. Green, of Butte.

Butte, July 16.

## NEVADA

### ESMERALDA COUNTY

(Special Correspondence.)—Because of the unwillingness of some of the creditors to wait longer in presenting their claims, negotiations for the transfer of the control of the Florence mine to the Red Hill Florence Co. have been discontinued.

The Silvermines Co. is erecting a 250-ton mill at its Great Western mine, at Hornsilver. The incline shaft is being sunk to 800 ft. A large tonnage of profitable ore is stated to be exposed. S. H. Brady, of Reno, is manager.

Goldfield, July 16.

(Special Correspondence.)—Shaft sinking at the White Caps has been discontinued; though drilling for a sump is in progress. The last few feet in the shaft passed through the quartzite into easier ground, and progress has been more rapid.

ings, still remains strong with high-grade ore in the face. It was reported that a fault had displaced the eastern segment, as a pronounced torsion in the foot-wall caused the limestone to appear in the face of the drift; but it was demonstrated that the ore occurred back of the raise in the foot-wall, and the drift has penetrated the orebody for 35 ft., with no sign of the end. Some remarkable samples recently were taken. The soft manganese ore assayed \$1294. The first 9 ft. next to the hanging wall went \$75.40; 9 ft. next to the foot-wall, \$10, making an average of \$42.70 for the 18 ft. across the vein, with more ore in the hanging not yet uncovered. A sample of the hard rock taken from the face of the drift returned \$370 per ton in gold. It is the intention to drive on the vein 50 ft., and then to cross-cut the orebody from hanging to foot-wall.

At the Red Top a pump-station is being cut, and the compressor foundations are in. The east cross-cut 25 ft. from the shaft shows an increase in the value of the ore.

A new orebody has been exposed on the Mustang, 150 ft. south from the Train-Chase lease workings. A north-south cross-fissure in the schist has been developed from the surface which assays across 2 ft. \$36 in gold.

Manhattan, July 14.

(Special Correspondence.)—The Morning Glory Co., which a few months ago began sinking on the outcrop, has now

reached a depth of 170 ft. on the incline, in shaft No. 1, and a second shaft, No. 3, started later, is down 55 ft. Both shafts have had ore from the surface, some of it being high-grade. The shafts, which are both in the hanging-wall side of the vein, are 60 and 30 ft., respectively, from the White Caps side-line. At the bottom of the deeper shaft, known as No. 1, 5 ft. of ore runs \$5 per ton in gold. In shaft No. 3 there is 2 ft. of \$26 ore, and the vein is widening with depth. It is interesting to know that in the days of the early excitement at Manhattan in 1905, the prospectors, almost without exception, assumed that the strong outcropping quartzite strata were valuable veins, but experience has shown that the quartzite contains little payable ore. The valuable ore deposits are replacements of the limestone strata, and this fact accounts for some of the veins now worked being so close to the side-lines of the claims. The Morning Glory is a good example of this state of affairs. The Morning Glory is being developed under the direction of F. B. Caldwell, who outlined the plan of development after an examination of the complicated geological structure of the district several months ago, and this plan has been endorsed by W. H. Wiley, who recently made an examination of the Morning Glory and several other properties in the district.

Manhattan, July 18.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The district tonnage for the past week amounted to 2500 tons. Development work is being carried on in all the principal mines. The present price of silver is the highest for 20 years or more, and lower grade ore can now be handled at a profit. Daily shipments are being made from the Pacific, Little Charlie, and Johnson mines.

The Oaks Co. installed a hoist on the Central shaft during the week, the head-frame is nearing completion, and sinking for the general development of the central group will soon be under way. Driving is now being done from the first level. New ore is being found in the Maud S. mine and daily mill-runs are being made. The company also made a shipment from the Eberle mine during the week.

Mogollon, July 10.

## OREGON

### JACKSON COUNTY

(Special Correspondence.)—The cinnabar strike recently made in the Butte Creek district is situated in the eastern part of the county 20 miles west from Mt. Pitt. This district is of recent volcanic formation, much broken up, and where mineral has never before been discovered. The first strike was made in basalt on the Terrill ranch six miles south-east of Eagle Point, the nearest railroad shipping place. The vein or dike contains cinnabar and assays high in quicksilver. Since the first discovery the dike has been traced for several miles north and south, and running from 100 to 200 ft. wide. It seems to be an extension of the cinnabar dike in Ramsey canyon, and in Meadows district. The new strike has caused many claims to be located. The new find extends in a heavily timbered region on the slopes of the Cascade mountains.

F. F. Childers, manager of the Greenback mine, says that the new equipment now at the property will be installed and ready for operation this fall. Modern machinery has displaced much of the old plant, which has been electrified. Four other properties besides the Greenback are under his management; the Jim Blaine, the Elk Basin, and the Illinois River properties. Three of these are copper, the others being gold. The new truck road to the chrome deposits in western Josephine county runs within three miles of the Illinois River properties; a connecting road will be constructed.

The war-time prices have given an impetus to the development of the sulphur deposits 45 miles north-east of Gold Hill, on the farm of W. T. Grieve, near Prospect. He is preparing

to put it on the local market for fertilizer. It is being used extensively in this valley for that purpose.

Gold Hill, July 16.

### JOSEPHINE COUNTY

(Special Correspondence.)—The Gold King mine, 6 miles west of Kerby, after a long idleness has been re-located by T. P. Johnson and Mrs. J. M. Finch. The mine is being unwatered. There was considerable development done a few years ago, but it was given up. With modern machinery the new owners believe it will pay.

Kerby, July 16.

(Special Correspondence.)—On July 7 the final payment of \$60,000 cash was made on the Queen of Bronze copper mine by John Hampshire, representing the purchasers. Less than two years ago Hampshire saw the property and began negotiation for its purchase. An option for 90 days was granted in December, 1915, but the size of the property called for longer time, and in March, 1916, a working-bond was secured, expiring January 1, 1918. Under that bond work has been in progress up to last Saturday, when the final payment was made six months before it became due.

The property is purchased by John Towhy, R. B. Miller, John Hampshire, M. S. Boss, T. F. Ryan, and Roy H. Clarke. A corporation will be formed. Hampshire will remain general manager, with R. C. Crowell, superintendent; Roy H. Clarke, consulting engineer, and Edward Strong, foreman.

The full price paid for the mine was \$150,000. There has been shipped out of the mine in little over a year \$283,000 worth of ore. The shipments have averaged 9.48% copper, and gold, \$3.50 per ton. The property has been shipping 700 tons per month. The monthly pay-roll is \$12,000, of which \$4000 goes for hauling. The expense of transportation is \$4.25 per ton. This property, which had been turned down on account of the phyrrotite in the ore, has been paid for out of the mine itself. If the experiments now being conducted by the United States Bureau of Mines jointly with the State Bureau, looking to the perfection of a flotation-process of separating the phyrrotite from the chalcopryite, is successful, a much larger percentage of the ore can be shipped profitably. These experiments are being made at this and the Waldo mine, both companies assisting in the work. The process will be given to the public as soon as experiments have been completed.

Grants Pass, July 12.

(Special Correspondence.)—Local men who have had the Waldo copper mine leased for some time have sold their leases to the owners of the mine, who are repairing the concentrator and putting in new track in adit No. 4. They will soon begin operations.

The Queen of Bronze copper mine now has 80 men employed and the force is being increased as rapidly as miners can be obtained.

K. J. Khoeery and Chas. Johnson, who sold the Lily copper mine to M. A. Delano some time ago, received another payment on the property July 1.

Takilma, July 17.

(Special Correspondence.)—At the Boswell gold mine, three miles from Holland, a gas-engine has been installed to operate the Huntington mill, recently placed on the property.

Holland, July 16.

## UTAH

The mineral output of Utah in 1916, as announced in an advance sheet by V. C. Heikes, statistician for the U. S. Geological Survey, was as follows: Number of producing mines, 318; tons of ore treated, 13,920,643; gold produced, 172,938.06 oz.; silver, 13,253,037 oz.; copper, 240,275,222 lb.; lead, 201,490,075 lb.; recoverable zinc, 29,572,522 lb. Total value, \$89,268,684. This output as compared with that in 1915 shows an increase in every metal except gold, which was 1652.59 oz. less than in the previous year. The total increase in value was

\$34,163,614. The foremost county in the State was Salt Lake, which produced in 1916 metals valued at \$68,797,428; Juab county coming next with \$8,696,661.

## WASHINGTON

### SPOKANE COUNTY

Tailing from the mines in the Wardner-Kellogg district in Idaho are to be used in the construction of a highway in Spokane county this summer. The tailing is obtained free, the only expense being the freight.

The tailing is to be used in the paving of four miles of the Truax road leading out of Fairfield. The county will require approximately 250 carloads of tailing. This material was used in the construction of a highway out of Fairfield 10 years ago, and for the paving of the principal streets in Fairfield and Rockford, and has proved to be the best and most lasting ever placed in the county.

Spokane, July 10.

### WHITMAN COUNTY

(Special Correspondence).—The Washington School of Mines is given an important place in the reorganization of the Washington State College, at Pullman, 55 miles south of Spokane, perfected by the board of regents at its last meeting and recently announced by President E. O. Holland. Under the new plan the mining branch becomes one of the eight colleges of the university and Professor Francis A. Thompson, head of the mining department, becomes dean of the School of Mines. Facilities will be available for instruction in the treatment of ores by standard methods, including amalgamation, concentration, roasting, smelting, and leaching. A special laboratory will be devoted to the flotation-process.

Spokane, July 2.

### STEVENS COUNTY

(Special Correspondence).—The Electric Point Mining Co. has paid a dividend of \$23,805 at its office at Northport. This will be at the rate of 3c. per share on an issue of 793,500 shares and will increase the total of disbursements to \$47,810, all made within a year. An intention of maintaining a surplus of \$100,000 was announced several months ago.

Spokane, July 2.

## CANADA

### BRITISH COLUMBIA

John O'Connell and Tony Angelo have a large quartz vein two miles north-west of the Emancipation group on the same contact. Their claims carry considerable free gold and will be developed. There is a good deal of ground prospected between the Emancipation and the O'Connell claims, but so far it has not been staked. There is also said to be a large area of gold-bearing country in the vicinity of the Coquahalla river that has not been prospected for quartz although some of the small streams have been worked for placer gold.

It is generally believed that the railway transportation now afforded by the Kettle Valley railroad will result in important development in the mineral region of the Hope, with the opening up of many new and valuable claims and the establishment of several permanent towns.

(Special Correspondence).—A new compressor-plant, with a capacity of 1500 cu. ft. of air and a 300-hp. electric motor is being installed at the Granite-Poorman mine, at Nelson. The company will have power enough to treble its output of ore. In the concentrating section of the mill four new tables have been added, which gives the mill a capacity of 100 tons per day as far as concentrating is concerned. The amalgamation and stamp department of the mill will be improved later.

Thirty-five men are employed at the property. F. H. Skeels is superintendent; A. G. Larson, of Spokane, is consulting engineer for the company.

Spokane, July 10.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

C. ERB WUENSCH is in Nevada.

THOMAS KIDDIE is at Vancouver, B. C.

EDSON S. BASTIN is in South America.

SEELEY W. MUDD is visiting San Francisco.

R. H. TOLL is examining mines at Chloride, Arizona.

R. E. CLAPP has returned from Carson City, Nevada.

LUCIUS W. MAYER, of New York, is in San Francisco.

CLEMENT H. MACE, of Denver, has been commissioned captain in the Engineer Officers Reserve Corps.

W. M. HOLMAN of Minneapolis is in the Cripple Creek district.

HENRY M. PAYNE has been examining lignite deposits in Washington.

W. H. JANNEY is manager of the Republic mine at Hanover, New Mexico.

F. LYNWOOD GARRISON has returned from the West Indies to Philadelphia.

J. H. COLLIER has returned to San Francisco from Alaska and Montreal.

FORBES RICKARD has been examining an alunite deposit at Rico, Colorado.

G. C. CROWE is in San Francisco from eastern Oregon and western Nevada.

WAYLAND H. YOUNG has returned to San Francisco from northern Ontario.

A. CHESTER BEATTY is at the St. Francis hotel, having arrived here from India.

F. W. MACLENNAN, assistant-manager to the Miami Copper Co., is here on a visit.

A. R. WEIGALL has been appointed general manager for the Seoul Mining Co., in Korea.

A. P. COLEMAN, Professor of Geology in the University of Toronto, is in South America.

OSCAR LACHMUND, manager for the British Columbia Copper Co., has been in San Francisco.

SHIGETARO KAWASAKI, Chief Geologist of Chosen (Korea), is visiting our Western mining regions.

F. B. CALDWELL has returned to San Francisco from Manhattan, Nevada, and Sierra county, California.

ISSAKU GOTOH, metallurgist to the Mitsubishi company, in Japan, is visiting the steel plants of this country.

SIDNEY H. BALL sailed for Vladivostok on his way to Western Siberia on the 'Nippon Maru,' which left on July 18.

FRANK R. WICKS has succeeded W. H. JANNEY as manager of the mill of the Chino Copper Co. at Hurley, New Mexico.

W. C. PHALEN is in San Francisco. He will investigate the manganese deposits of California for the U. S. Bureau of Mines.

KOSAKU YAMADA, mining engineer to the Osarusawa mine, of the Mitsubishi company, is visiting our Western mining districts.

W. TOYOTE has resigned as examining engineer to Phelps, Dodge & Co. in order to engage in consulting practice at Tucson, Arizona.

P. N. MOORE, S. J. JENNINGS, B. B. LAWRENCE, J. PARKE CHANNING, and EDWIN LUDLOW are the representatives of mining on the Engineering Council, which is co-operating with the Government.

The next meeting of the San Francisco section of the A. I. M. E. will be held on the evening of July 31 at the Engineers Club, Denver, at 6:30; meeting at 8 p.m. A paper will be read by Professor D. M. FOLSOM on 'The Californian Oil Crisis.'

# THE METAL MARKET

## METAL PRICES

San Francisco, July 24

Aluminum-dust (100-lb. lots), per lb.	\$1.00
Aluminum-dust (ton lots), per lb.	\$0.95
Antimony, cents per pound.	15.50-18.00
Electrolytic copper, cents per pound.	29.50
Pig lead, cents per pound.	12.25-12.50
Platinum, soft and hard metal, per ounce.	\$105-111
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound.	10.50
Tin, cents per pound.	60
Zinc-dust, cents per pound.	20

## ORE PRICES

San Francisco, July 24

Antimony, 50% metal, per unit.	\$1.20
Chrome, 40% and over, f.o.b. cars California, cents per unit.	50-55
Magnetite, crude, per ton.	\$8.00-10.00
Tungsten, 60% WO <sub>3</sub> , per unit.	26.00
Molybdenite, per unit for MoS <sub>2</sub> contained.	40.00
Manganese, 45% (under 35% metal not desired), cents, unit.	33-37

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices paid of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburgh, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese.	Per unit \$1.00
46 to 49% metallic manganese.	0.98
43 to 46% metallic manganese.	0.95
40 to 43% metallic manganese.	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.25% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on lots of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

Tungsten: There is still a strong demand for tungsten ore and so far very little ore has come on the market. Such quantities as were disposed of during the past week were sold at increased prices ranging from \$22 to \$23 for wolframite, with scheelite selling on the basis of \$26, New York. Several large users are in the market for regular supplies of tungsten ores to cover the balance of this year and the early part of 1918, but so far, none of the producers who are not already sold out has been found willing to make a price on the present basis, looking forward to a much higher market.

## EASTERN METAL MARKET

(By wire from New York)

July 24.—Copper is lower and nominal at 26.75c. to 26.50c. Lead is dull and lower, at 10 to 10.25c. Zinc remains quiet at 8.37 to 8.50c. Platinum is unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
July 18.....	80.25
" 19.....	79.50
" 20.....	78.87
" 21.....	78.87

May ....	49.87	74.27	74.61
June ....	49.03	65.04	76.44

High-price records continue to be made for silver, the best figure to date being slightly better than 84c. per oz., for delivery on the Pacific Coast. Shortage of supplies in London and the fact that quotations emanating from that city still have their effect upon the world's silver market have combined to put the New York price up to its present high level. The lower rates across the Pacific than those prevailing to London and thence to the Far East and the absence of war risk insurance have made it almost obligatory on the part of the shipping companies to route their silver for India and China from Pacific Coast ports rather than from Montreal and New York.

England and France have been persistent buyers of silver for coinage, largely to pay off their troops in the field. The United States government has bought in the past two months about 3,000,000 oz. of silver, with further purchases thought likely. This also represents coinage requirements which should grow materially from now on.

## COPPER

Prices of electrolytic in New York, in cents per pound.

May ....	18.71	29.02	31.60
June ....	19.75	27.47	32.67

The copper-ore output in Japan in 1916 amounted to 111,562 tons, as compared with 83,017 tons in 1915 and 78,700 tons in 1914; while exports amounted to 57,402 tons in 1916, as compared with 55,528 tons in 1915 and 43,305 tons in 1914. Russia now buys 60% of Japan's copper exports; the United Kingdom takes 20%, while France, the United States, and India share the remainder. The consumption of copper ore in Japan has increased considerably during the last three years, amounting in 1916 to 59,690 tons, as compared with 27,723 tons in 1915 and 32,045 tons in 1914.

The July production of metals by the Anaconda Copper Mining Co. will be extremely small, owing to the strike, says the 'Boston News Bureau.' Not only has copper output dwindled to a minimum but the electrolytic zinc plant has materially cut down its operations.

Certain overhead charges must of course be maintained regardless of operations, while pumping and maintenance of good conditions at mines and plants entail heavy expenditures.

It is estimated that Anaconda's earnings during the first half of the year were in the neighborhood of \$23,000,000, based on 28c. copper and a 14c. copper cost, this item including all taxes and other extraordinary charges. Smelter production of copper was 163,000,000 pounds.

The United States Geological Survey gives the total production of smelter copper in the United States for 1916 at 1,927,350,848 pounds.

Last quarter copper has been offered at 27c. per pound, against sales for that delivery at 30 1/4 c. a short time ago. Bids have been asked for the closing three months of this year.

Copper for shipment in the first quarter of 1918, which has sold at 29 1/4 c. and better, may now be secured at 25 cents.

## LEAD

Lead is quoted in cents per pound, New York delivery.

Date	Average week ending
July 18.....	10.75
" 19.....	10.50
" 20.....	10.25

## Eastern Metal Market

New York, July 18.

Stagnation and demoralization characterize the condition of practically every metal except tin. Actual prices are hard to gauge, demand and orders being of small volume. The proposed one-price-to-all policy of the Administration has caused to halt a market which before that was decidedly lame and uncertain.

Copper is growing weak each day.

Tin is fairly steady with not much business.

Lead is sagging with consumers uninterested.

Zinc is stagnant and lower.

Antimony has again declined, demand being slack.

Aluminum is a little lower and dull.

In the steel market new business has decidedly slackened. The effect, on buyers, of the President's advocacy of putting all steel and metal buyers on an equal price-basis, and a lower one, has had just the effect which was to be expected. The one policy now is postponement of buying until the Federal Commission's cost-finding inquiry is completed. There is much speculation as to the effect of the new policy, and many varied opinions as to its practicability. The embargo on exports of certain steel products has held up some shipments, but vessel-space is really a more serious factor. Mill output has been less in July than in June, which also was less than May. The entire trade awaits the outcome of the vital controversy with anxiety.

### COPPER

Prices are falling and a decided weakness is looked for if not already here. The cause is not hard to determine. On Friday last week the President's statement, advocating the same price to consumers as well as to the Government for steel, metals, and other materials, came as a distinct shock. Its effect on the non-ferrous metal market has been pronounced, and prices have fallen daily. Added to the foregoing factor was the announcement that for the 60,000,000 lb. of copper recently bought by the Government at a provisional price of 25c. per lb., only 75% of it, or 18.75c. per lb., would be paid, the remainder, if any, to be determined by an investigation of costs. This was also an unsettling factor. Commenting on this phase of the subject, it is freely stated here among dealers that it is not likely that the Government will pay as high as 20c. per lb. for any of its future needs. If this is to apply to the Allies and all other consumers, then the future could hardly be more indefinite and uncertain. It is rumored that producers have refused to accede to the Government's position. Under such dominating influence it is a buyers' market. Consumers will not come into the market when lower prices are reasonably expected, and are holding back decidedly. Lower levels are generally looked for. One dealer states that he thinks any large inquiry would receive very favorable consideration, and be taken at most any price—at figures regarded as absurd only a week or 10 days ago. Prices are entirely nominal, the quotation yesterday for both Lake and electrolytic having fallen to 28c. for July delivery. For last quarter, opinions differ, offerings ranging from 24.50 to 25.50c., New York. The question of price fixing is so important and far reaching a matter that it is fraught with many disturbing factors. The fact should not be lost sight of that there are many consumers who are under contract to buy millions of tons of copper for delivery this year and into next year at almost 25c. per lb. What is to be their status if the general price is fixed at under 20c. per pound? The London market is unchanged at £142 for spot and £138 for future electrolytic metal.

### TIN

This metal is the only one that exhibits any steadiness. While the market the past week has been a narrow one, it has

behaved unexpectedly well in comparison with copper, lead, and zinc. The deliberations or decisions of the Tin Committee have not been made public, and have not been a factor, but the unsettling of the other markets by the President's advocacy of a one-price-to-all policy has had its effect and has unsettled business. Many think that if a general price re-adjustment by compulsion is to result, it will be stupendous and that a business depression is not improbable. The tin market in such an event would suffer with the others. The latter part of last week a fair business was quietly done in futures, and early this week a moderate business for the same position is reported. There has been some demand for spot Straits, but it has not been large. Prices have ranged from 63 down to 62c., New York, on Monday, with the quotation yesterday at 62.50c. Stocks of Straits tin are heavier than last week. Arrivals up to July inclusive are reported at 1925 tons, with the quantity afloat at 3729 tons. The London market has declined in the week about £8 per ton, the quotation yesterday having been £239 10s. for spot Straits metal.

### LEAD

What has been said about copper applies equally well to lead. The one-price-to-all policy has weakened the market and buyers are extremely cautious as to their commitments. They naturally expect, after such a public avowal from a high source, much lower prices, especially because the recent Government purchase was fixed at 8c. per lb. The tendency is decidedly lower with producers holding the market up as near 11c. per lb., New York, as possible. Early delivery metal today is quoted at 10.50c., New York, and 10.37½c., St. Louis, but the American Smelting & Refining Co. still maintains the quotation at 11c., New York. Small sales have been made, but aloofness on both sides is the attitude. One carload is reported to have gone at 10.37½c., New York. The future of the lead market is uncertain and extremely hazy. Strikes in the West have added to the difficulties of the situation.

### ZINC

There may be less gloom in the zinc market than in most of the others, but if so it is because it is believed that prices have reached so low a state that a definite fixing of them by the Government would put them higher instead of lower if settled upon a cost plus a reasonable profit basis. It is generally recognized that a price below 9c. per lb. is in many cases less than cost and hence not a fair basis for the industry as a whole. Owing to recent and past edicts from Washington as to prices in general, quotations for prime Western spelter are chaotic. In the words of one dealer: "They are all over the map." One sale of 100 tons for early delivery is said to have been made at 8.62½c., St. Louis, or 8.87½c., New York, while another went at 9c., St. Louis, or 9.25c., New York. But the volume as a whole is insignificant and no guide as to real values. Consumers will not buy under present conditions nor will producers commit themselves far into the future. The little business done is all hand to mouth. A fair estimate of present prices, which are mostly nominal, is 8.62c., St. Louis, or 8.87c., New York, for early delivery, with future shipments higher if anything. The fact that the Government bought sheet-zinc at 16c. per lb., or 3c. under the market, is pointed to as not at all in line with other conditions in the zinc market and as really a boon to sheet-zinc makers. They are said to be highly satisfied with their bargain.

### ANTIMONY

A further decline is recorded in the face of small demand and a stagnant market. Chinese and Japanese grades are offered at 16 to 16.50c., New York, duty paid. Possibly 15.50c. could be done.

## Company Reports

### ALASKA UNITED GOLD MINING CO.

The annual report of the Alaska United Gold Mining Co. for the year ended December 31, 1916, shows the following: At the Ready Bullion mine 286,078 tons of ore was crushed producing in free gold \$235,846.89, and base and copper bars to the value of \$27,813.59. Concentrate treated, 6629.77 tons, which produced \$338,533.83, making a total production of \$602,194.31. Mining cost (377,547 tons stoped) was \$0.9983 per ton. Milling expense (286,078 tons milled) was \$0.344 per ton. Sulphide expense (6629.77 tons treated) was \$0.1209 per ton milled. Total operating cost including various sundries, \$1.5118 per ton, a total of \$432,504.63. Construction costs were only \$0.0026 per ton milled.

At the 700-Ft. claim 262,850 tons was crushed, producing \$179,861.72 or at the rate of \$0.6843 per ton. Base and copper bars yielded \$0.0612 per ton treated, making \$16,082.72. Concentrate treated, 5341.98 tons, yielded \$0.9906 per ton of ore crushed, amounting to \$260,375.48. Making total receipts from all sources of \$456,319.92.

Mining cost \$1.8128 per ton, and included 7771 ft. of development, and 284,566 tons stoped. The 700-mill crushed 262,850 tons; 5341.98 tons of concentrate was saved, the cost of treatment of which was \$30,771.35 or at the rate of \$0.1171 per ton of ore treated. The total operating and construction cost at the 700-Ft. mine was \$623,913.36, or at the rate of \$2.3737 per ton treated. The net loss for the year at this mine was \$167,593.44.

### MOUNT BOPPY GOLD MINING CO., LTD.

The annual report of the Mount Boppy Gold Mining Co. (Limited), Cobar district, New South Wales, for the year ended December 31, 1916, shows the following:

In 1916, 72,420 tons of ore was milled, which produced, by amalgamation, 10,172 oz. of bullion; 12,474 tons of tailing treated yielded 3253 oz. of bullion, and 55,010 tons of slime, 15,263 oz. of bullion; in addition to which 1600 oz. of fine gold was recovered from 361 tons 4 cwt. of concentrate; the total production being 30,288 oz. of bullion, or 20,512 oz. of fine gold, of a realized value of £85,837 17s.2d.

Sundry receipts, including interest and discount, and transfer fees, brought up the total income to £87,591 12s.3d. The expenditure on revenue account amounted to £95,314 19s.4d., and a balance of expenditure for the year of £7723 7s.1d.

The chief factors militating against the regular working of the mine, rendering the conditions abnormal, and accounting for the unusual occurrence of a loss being shown instead of a profit were:

(a) A shortage of labor and the consequent curtailment of development and stoping operations; (b) the lower average grade of the ore milled; (c) an unusual rainfall, which was almost continuous throughout the 12 months; (d) the temporary closing down of the mine on two occasions owing to strikes by the engine drivers and firemen for increased wages.

With regard to the shortage of labor, this was due to some 30% of the best of the employees having joined the army. These men readily responded to the appeal of the military authorities, thus showing a sense of their appreciation of their duty toward the mother-country.

### NEVADA WONDER MINING CO.

The tenth annual report of the Nevada Wonder Mining Co. for the year ended December 31, 1916, shows the following: Development work during the year, 10,509 ft. The sub-shaft was completed from the 1300-ft. level to the 1600-ft. level. The average amount of ore treated in mill daily was 157 tons.

Total ore treated 72,241 tons from which was recovered 10,933 oz. gold, and 1,243,763 oz. silver. The average value of the ore treated during 1915 was 0.159 oz. gold, and 18.72 oz. silver. For silver the average price received was \$0.647 per ounce.

### DETAILS OF COST

	1916
Total mining cost per ton of ore, including transportation .....	\$ 5.33
Total milling cost per ton of ore.....	3.31
Marketing cost per ton of ore.....	0.26
Total cost per ton.....	\$ 8.90
Average value per ton of ore.....	15.40
Loss in tailing per ton of ore.....	1.13
Recovery per ton .....	\$14.27
Less total cost per ton.....	8.90

Profit per ton of ore mined and milled.....\$ 5.37

The following improvements were made during this period: A new Ingersoll-Rand No. 5 drill-sharpener, with full equipment for sharpening all kinds and sizes of steel.

A new 50-hp. double-drum electric hoist was placed in operation at the sub-shaft to enable the sinking of this shaft to the 1900-ft. level.

There has been installed a Vulcan, 1000-lb. per day, ice-plant, which has proved a great benefit and comfort to the employees; an electric tractor on the 1300-ft. level for moving ore from the stopes, and waste from the sub-shaft; five piston-drills, 11 stoping-drills in the mine, 2 air-hoists, and 30 one-ton mine cars.

### THE TONOPAH MINING COMPANY OF NEVADA

The fifteenth annual report announces dividends to date since April 1905 of \$13,750,000, including the last paid on December 18, 1916, of \$150,000. In addition the company has retired its outstanding preferred stock, amounting to \$380,557.51. During the year 1916, 74,991 tons of ore was mined, and the Desert mill treated 81,782. Also 5542 tons was shipped from the dump. The average gross value of the ore milled was \$15.65 per ton. The estimated tonnage blocked at the end of the year was 72,100 tons, assaying \$16.74 per ton, making reserves valued at \$1,206,821. The average cost per ton of mining and milling the ore and marketing the products for the year was as follows:

Mining and handling dump-ore.....	\$ 4.61
Milling .....	3.16
Freight on ore milled.....	0.72
Marketing product .....	0.22

Total cost per ton .....	\$ 8.71
Metal losses in milling and refining.....	1.34
Profit per ton .....	5.60

Average gross value of ore milled.....\$15.65

The report of F. F. Heydenfeldt, superintendent of the mill, states that the ore treated carried 15,636 oz. gold, and 1,387,557 oz. silver, of which 94.2% of the gold was recovered, and 90.3% of the silver. The recoveries were less than during the previous year, owing to the delivery to mill of ore containing manganese-silver compounds that are not amenable to treatment with cyanide. The amount of silver so locked up was not large enough to repay the cost of the additional treatment that would have been required for its recovery. The increased cost of treatment was due to higher costs of supplies. The milling cost rose from \$2.61 in 1915 to \$2.767 in 1916. Of this difference of 15.7c. per ton 9.2c. was due to the higher cost of cyanide, and 6.5c. to other supplies. The mining cost, under W. H. Blackburn, mine superintendent, was \$3.94 per ton, plus 67c. indirect cost.

the purpose of demonstrating its capabilities. The conditions on this road are similar to those existing over the Allegheny mountains, namely, mountainous country, steep grade, and heavy traffic. The electrical characteristics of the Norfolk & Western are also similar to those of the Pennsylvania railroad locomotives, that is, 11,000-volt, single-phase, 25-cycle current.

The locomotive is of the familiar side-rod type, built in one unit, with the cab extending over the two trucks. Each truck has six 60-in. driving-wheels, and has mounted on each two induction-motors. The two motors on each truck are geared to a spring-gearred jack-shaft, which in turn is connected to the driving-wheels by means of the side-rods. Single-phase current is supplied from the trolley wire at 11,000 volts to the transformers, which reduce it to a lower voltage. From here it is delivered to a phase-converter, which in turn changes the energy into three-phase current for application to the induction-motors.

The weight of the locomotive is 260 tons and the length is 76 ft. Notwithstanding this weight the engine is much easier on the road-bed and track than a steam-locomotive because the weight is cushioned and the running-gear perfectly balanced from all speeds, due to absence of reciprocating-parts.

The engine is designed for normal running speed of 20.6 miles per hour, which is considered sufficiently high for the mountainous country, steep grades, and heavy traffic to be encountered. A speed of 10.3 miles per hour, obtained by connecting the motors in 'cascade' is used for slow movements such as around the yards.

The control is effected in a simple manner by the use of water-rheostats. With such success has this control been worked out that power can be applied so gradually as to enable the engine to start a long train without any jerks.

One of the most interesting features of this locomotive is the automatic regenerating braking, which permits the train to descend the grade at the same constant speed at which it ascends, and without the use of the air-brake. The induction-motors on this locomotive have such inherent characteristics that they will transform the electric energy from the line into mechanical energy for hauling the train up the grade. As soon as the train begins to descend, the energy produced by gravity automatically causes the motors to act as generators, and in turn produces electric energy which is sent back into the line, and can be utilized by other ascending trains. Not only does this mean a saving in power, but it adds another safety-first feature, by permitting the air-brakes to be held in reserve for use in emergency and only in bringing the train to a complete stop.

The concentration of this enormous amount of power in a single cab-unit of the above dimensions, is very much in excess of anything heretofore attempted. This large saving of weight and space, when compared with previous electric locomotives, and especially with the steam-locomotives with its tender, has only been accomplished after very careful and painstaking design on the part of the engineers.

## A New Californian Mining Enterprise

The foundation for a new amalgamation and concentration mill is in place and the building is being rushed to completion, on the Rincon mining property, 50 miles south of Needles, in San Bernardino county, California. This mine is owned by W. J. Farr and McDowell Bros., of Parker, Arizona. A 100-ton Denver steel crusher will be installed, but the balance of the machinery will have a capacity of 25 tons per day, which will be added to as development work at the mine proceeds.

The order for the equipment has been given to the Denver Quartz Mill & Crusher Co., of Denver, Colorado, for early shipment and the mill is expected to be in operation by September 1. The owners of the mine will also operate a boat on the Colorado river from Parker, Arizona, to the company's prop-

erty which, besides carrying freight and passengers, will be used to transport the concentrate from the mill to Parker, where re-shipment will be made by rail to the smelter.

## Large Contract for Soot-Cleaners

The Vulcan Soot-Cleaner Co., through the De Ved-Kissick Co., its New York representatives, has recently closed a contract for soot-cleaners for 98 boilers for a group of electric light, power, and railway companies, controlled by the H. L. Doherty Co. The boilers are of various types, including a large number of Stirling make. The general recognition among engineers of the efficiency of mechanical soot-cleaners as compared to hand-blowing is indicated by this and similar recent orders for the entire equipment of large plants and groups of plants. The continually rising price of coal is also accountable for the placing of these orders.

## Commercial Paragraphs

The GENERAL ELECTRIC Co., of Schenectady, New York, has issued Bulletin No. 46,209, descriptive of the Thomson direct-current astatic watt-hour meters, and Bulletin No. 42,014, describing headlights and turbo-generators for steam locomotives. Both bulletins are profusely illustrated.

The SPRAGUE ELECTRIC WORKS, of the General Electric Co., has issued two bulletins, No. 48,700A, describing the Sprague mono-rail hoists, which are cage-controlled and No. 48,923, that describes the electric hoist type W, of one to six tons capacity. These bulletins can be obtained by addressing the Sprague Electric Works at any of their offices in the principal cities of the country.

The WALTER A. ZELNICKER SUPPLY Co. and affiliated companies are now represented in the Birmingham district by Thomas A. Hamilton, who for the past 14 years has been connected with the Crane Co., prior to which he was superintendent of the Zelnicker car works, East St. Louis plant. Mr. Hamilton will have charge of both the buying and selling in the south-eastern territory. His office will be at 1018 Woodward building, Birmingham, Alabama.

Harry E. Dennie, for many years connected with the rubber industries, has been appointed general manager for the IMPERIAL BELTING Co. Mr. Dennie was previously living in Chicago, where he has many friends who will be pleased to learn of his success. Prior to coming to Chicago and for some time back he was on the Pacific Coast as manager of the company's interests west of Denver. W. S. Bloomer, who has for the past 24 years been connected with one of the largest rubber manufacturers, was also originally at Chicago, and previously was at Seattle, as Pacific North-West manager for this company. Recently he was appointed general sales manager for the Imperial Belting Co., with headquarters at Chicago.

The GENERAL FILTRATION Co., of Rochester, New York, has issued a new book descriptive of filtros, the purpose of which is to give to those who are not familiar with it, an idea of what filtros really is. Filtros is a white, rigid, porous mineral substance composed essentially of silica, and may be best described as an artificial porous stone. It is manufactured from a selected natural sand, the composition of which is 99.6% silica. The bonding-agent is synthetic silica, which fuses at 2000°F. Filtros is employed extensively in the filtration of various liquids from which it readily separates any solids held in suspension. It can be used in containers of any size, from the ordinary water-faucet to great tanks holding thousands of gallons. Those who have filter-problems still unsolved would do well to send to the General Filtration Co. for this interesting little book.

Science has no enemy save the ignorant

Issued Every Saturday

SAN FRANCISCO, AUGUST 4, 1917

\$4 per Year—15 Cents per Copy

## TABLE OF CONTENTS

Page.

### EDITORIAL

Page.

NOTES ..... 149

THE THIRD ANNIVERSARY ..... 150

The beginning of the fourth year of the War. Why we kept out of it so long and why we are fighting now. M. & S. P., August 4, 1917.

OIL LEGISLATION NEEDED ..... 151

Comment on the report of a committee of the Californian State Council of Defense. The need for prompt action. M. & S. P., August 4, 1917.

THE NITRATE FIZZLE ..... 152

The delay in establishing a plant for the fixation of nitrogen, despite legislation by Congress. The mistaken supposition that our chemists do not know how to go to work in creating a source of nitrogen suitable for the manufacture of explosives. M. & S. P., August 4, 1917.

### DISCUSSION

#### PATENTS.

*By John Nicol* ..... 153

A criticism of the patent law, by an engineer. The value of an invention. The grant of a monopoly. A suggested re-organization of the Patent Office. Classification of patents and gradation of privileges accorded therewith. M. & S. P., August 4, 1917.

#### NOTES ON FLOTATION.

*By Paul T. Bruhl* ..... 155

Interesting details concerning flotation practice in the mill of the Nevada Copper Consolidated Company at Ely, Nevada. M. & S. P., August 4, 1917.

### ARTICLES

MIAMI, ARIZONA: THE DISCOVERY—I.

*By T. A. Rickard* ..... 157

The first of a series of articles on mining and metallurgical practices in the Miami district. How the big orebodies were discovered and appreciated by F. C. Alsdorf and J. Parke Channing. The financing of the exploratory operations. Outlines of the local geology. M. & S. P., August 4, 1917.

THE RUSSIAN CRISIS.

*By Charles Janin* ..... 163

Notes from a Californian engineer recently returned from Petrograd. The beginning of the Revolution and the causes of it. Economic and financial conditions in their effect upon mining. Prospects for American enterprise in Russia. M. & S. P., August 4, 1917.

FLOTATION—THE BUTTE & SUPERIOR CASE—II..... 168

Excerpt from the brief for the defendant. The supposed 'critical' point. Effects of using more than 1% of oil on the ore. M. & S. P., August 4, 1917.

CALIFORNIAN COMMITTEE ON PETROLEUM ..... 171

Abstract of report of conclusions and recommendations by the Committee on Petroleum of the California State Council of Defense. M. & S. P., August 4, 1917.

### DEPARTMENTS

REVIEW OF MINING ..... 173

Special Correspondence from Toronto, Ontario; Mayer, Arizona; Leadville, Colorado; Silver City, New Mexico; and Cripple Creek, Colorado.

THE MINING SUMMARY ..... 178

PERSONAL ..... 182

THE METAL MARKET ..... 183

EASTERN METAL MARKET ..... 184

Established May 24, 1860, as The Scientific Press; name changed October 20 of the same year to Mining and Scientific Press.

Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bdg.; New York, 1760 Woolworth Bdg.; London, 724 Salisbury House, E.C.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

# Speed up with Electric Power

*G-E Equipment is reliable and economical*

**H**ERE are some of the ways in which modern industry has been speeded up by putting electric power to work in the right place.

Metal mines have boosted output to meet worldwide demands. Great central power plants in place of small local plants in coal mining areas now supply cheaper electric power per ton output for each mine. All tonnage records have been smashed in the steel industry. Greater automobile output has lowered prices and given better road transportation. More and better cloth has been produced at lower power costs.

The engineering problems solved in putting electric power to work in these and other industries were many and intricate. Production of electrical equipment suited to this work and in quantities required is an important part of this company's service to American industries.

Any problem involving the use of power can be simplified by the application of electricity. The General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to co-operate with manufacturers and engineers in every possible way.

# EDITORIAL

T. A. RICKARD, Editor

NOTHING seems to have been decided about the Government's purchase of copper, mainly because the producers of this metal do not see why they should accept so low a price as 18½ cents per pound at a time when the producers of other commodities are not asked to make a similar sacrifice. Meanwhile it is reported from Utah that three Federal inspectors have arrived from Washington to examine the books of the copper companies with a view to ascertaining the exact cost of producing the metal.

TYPOGRAPHICAL blunders are annoying to the reader, but we can assure him that they are far more annoying to the author and editor. In an article on 'The Principles of Flotation,' in our issue of July 7, the author was made to say that surface-tension was equal to "3.14 grammes per linear inch or 72.62 dynes per centimetre at 20°C." By that perversity which one of our Allies would call *la malice des choses* the word 'grammes' had been substituted for 'grains.' Of course, no careful writer would use 'grammes' with 'inches.' We are reminded of an equally irritating error that appeared in Mr. T. J. Hoover's book on flotation, in which, when quoting from Clerk Maxwell's article on 'Capillarity' in the *Encyclopædia Britannica*, the measure of surface-tension was spoiled by inserting the word 'square' before 'centimetre' in the phrase "81 dynes per centimetre." Eternal vigilance is the price of safety.

RUSSIAN affairs are of such engrossing interest at this time that we are glad to publish a record of recent observations made by Mr. Charles Janin in the course of a journey to Petrograd by way of Siberia. Excellent accounts of the revolution in Russia have been published, for example, in the *New Republic*, but to our readers an article by one of themselves, by a mining engineer, will have a particular value. Most of us are curious to know how things look to one having a mental bias like our own. Since the happenings described by Mr. Janin the Russian position has undergone several changes and the future of the new democracy has been darkened by the excesses of its friends no less than by the efforts at reaction on the part of its enemies. The national crisis has produced a strong man, A. F. Kerensky, who, if he is supported loyally, is likely to establish a stable government and organize an effective army. We confess to a feeling of optimism, despite the prevailing gloom. The Russian peasant is docile and mystical, as well as courageous and enduring; if the friends of liberty can succeed in establishing order out of chaos then Russia will play her proper part in a war that to

her is no longer one of territorial expansion or political aggression. The sympathy and help of the American nation will go far to promote that result.

FURTHER protection for the public from the wiles of fraudulent promoters is promised by means of the new Blue Sky law, or Corporate Securities Act, which went into effect in California on July 27. The former law was avoided by registering wild-cat companies in other States and then peddling their stocks in California, thereby evading the discipline of the State Corporation department. The new law, drafted by Mr. H. L. Carnahan, the Commissioner of Corporations, who has done the public a great service ever since he assumed this responsibility, compels every person or company engaged in the sale of securities in this State, whether issued originally here or elsewhere, to obtain a certificate authorizing him or it to act as a broker. Such broker must bear a good reputation in order to obtain a license, which may be revoked if he engages in a fraudulent transaction. The law provides also that copies of all advertising matter relating to the sale of securities issued or published by brokers must be filed with the Commissioner, and the circulation or publication of such matter if interdicted is punishable by law. We congratulate Mr. Carnahan on the further powers thus granted to him in pursuance of his good work, for, while the last to discourage mining ventures even of a risky kind, we are as anxious as he is to stop the diversion of good money into fraudulent schemes. The more capital given to frauds the less there is for legitimate business.

THE editor of the 'Colorado School of Mines Magazine' sends us a marked copy of his July issue, containing a reply to the account of the recent trouble appearing in our issue of June 16. We have read this reply carefully and patiently. Our critic is in error in supposing that because the present writer was at Golden "a short time on Commencement day" he was unable to elicit the facts and that "he pretends to quote the students." The writer was at Golden longer than his critic supposes and he discussed the matter with a number of students, not all of them at Denver. The School has graduates all over the West and the matter was discussed with some of them, as well as with other persons thoroughly informed concerning the events that have given the School a temporarily unpleasant notoriety. The editor of the Magazine undertakes to defend the three trustees whom we criticized as unfitted for their responsibilities; we do not begrudge them a defence and we do not care to return to the attack by making further comment. Our criticism of them was, we believe, true

and in the best interests of the School. One mistake we did make in referring to the other trustees: Mr. F. G. Willis is not an alumnus, but he is a mining engineer in good standing in Colorado, and this fact serves equally well for the purpose of our argument. Our humorous comparison with the strike at Telluride was borrowed from a mine-manager at Telluride and the quotation concerning the students "willingness to work in harmony with the faculty" was taken verbatim from the published statement of a student. The editor of the Magazine would have done better by using his columns in appealing to the alumni to support the faculty and warn the students that their unruliness has besmirched the reputation of the School.

**M**INING just across the border in Mexico is still rather mixed. Cananea remains closed, although negotiations are in progress with Governor P. Elias Calles for a settlement of the trouble. Nevertheless the bulk of the laborers have been shipped south by order of the Governor, ostensibly to prevent food-riots. This action cannot well be criticized, because the cessation of work and of importation of supplies would quickly result in starvation. On the other hand, the scattering of several thousand workmen will make the re-organization of a crew more difficult and costly, although the availability of so many men will be of immediate benefit to the farmers. It has been increasingly difficult to obtain farm-labor in Mexico, and it will be noted that the shut-down at Cananea came just at the period for planting corn in that part of the world. After this will follow the bean-planting. There is work to be done from this time throughout the summer and autumn, and the newly-favored holders of confiscated estates will be highly pleased to have so many peons thrown upon the country. This is not suggested as a motive for the pressure brought to bear upon the mining companies, but it is a feature of the situation that may not be disregarded. It is quite certain that these men will be of such use as producers of food as to outweigh the importance of the mines to the State, and those that are favored by the authorities will profit in consequence. The troubles at the Tigre mine near Nacozari are 'officially' settled, so far as gubernatorial promises go, and the technical staff has returned to re-open the property. In this case, however, it must be noted that the number of workmen is less, while the output is of exceptional value, the ore being rich in silver. The local government is said to have attempted to produce from this property on its own account, but the plant is operated throughout by electricity transmitted from the Phelps-Dodge generating station at Douglas, Arizona. It was, accordingly, impossible to turn a wheel, and it was equally impossible to install a steam-plant adequate either for mining or milling. The heavy taxes upon the silver shipped by the company are worth more than the net value of any product that the Mexicans could obtain by working the mine. This would offer a reason for special concessions to this company. Governor Calles has the reputation of

being more favorable to American enterprise than his predecessor, Governor de la Huerta, who was a Carranza appointee.

## The Third Anniversary

On August 2, 1914, the German army invaded Belgium. Today 20 nations are in a state of war, including all the supposed leaders of modern civilization. To thoughtful men in every country the catastrophe has seemed appalling; to them the three long years have been a nightmare of horror. To many of our own people the crowning event of participation in the struggle is so new that the decisive action of a President elected 'because he kept us out of the War' is still a bewildering event rather than a logical consequence. The thoughtless—and there are plenty of them—are asking even yet why we did it. The President has said: "It is a fearful thing to lead this great peaceful people into war, into the most terrible and disastrous of all wars." It was. His decision to do so was the result of a judgment as deliberate and painful as history records; the United States became the declared enemy of Germany only after trying every device of diplomacy and enduring the full measure of insult. We saw Belgium made a road for the gray swarm of the invader, and did nothing; we held our hand even after helpless populations were driven into slavery by the ruthless conqueror; we only protested when our citizens were murdered on the ocean; we hesitated to interfere because we loved peace and abhorred war; to us the catastrophe was already so tremendous that we hated to enlarge the scope of it; we had inherited an honorable tradition of non-interference in European troubles; we hoped to do more good to suffering humanity by helping the victims of war than by increasing the number of them through going to war ourselves; we dreamed of playing the part of peace-maker. At the end of last year the President gave the German government an opportunity to state its purpose and to justify its claim that it was waging a defensive campaign. The answer disclosed a plan of impenitent aggression, the objects of which were the subjugation of Belgium and the permanent occupation of a part of France, to destroy the freedom of the one and to seize the iron mines of the other, to extend German hegemony over the weaker nations of south-eastern Europe, and to accomplish this not only by ruthlessness on land but by the destruction of the merchant shipping of the neutral countries. That did it. We could no longer remain detached from the great struggle.

On April 6 we entered the fight "to make the world safe for democracy," as the President announced. In March one of the few surviving autocracies had been swept aside and Russia stepped through the darkness of revolution into the light of liberty. Thus the four principal Allies are united in their political ideals. But some organs of misinformation, like the *San Francisco Chronicle*, assert, "To say that we are fighting for democracy is nonsense. We already have it, and we are

certainly not at war to compel others to accept it." Yes, we have democracy, but how long should we preserve it if the German purpose prevailed in Europe, if the French army were overcome and the British navy destroyed? The democracies of Europe are fighting to preserve the democratic ideal as against the insistence of autocratic absolutism; they are fighting for the freedom to live and let live against the paranoiac insanity of Junker militarism. Is that no concern of ours, seeing that we are threatened by a visitation of the same pestilent policy if England and France are beaten? There is no danger of that, says our *ignoramus*. The Allies will win. We believe it, but the result is too vital to be left to the slightest uncertainty. And if they win, are we to allow them to do all the fighting? No, we are going to do as Washington and Lafayette, as Lincoln and Lee, would have done. Even if we had so little sympathy with other peoples as to make a political island of ourselves; even if we attempted—under the leadership of men as ignorant as he of the *Chronicle*—to ignore the wrongs perpetrated on other democracies; even if we were willing to "pass by on the other side" while the people of Belgium were enslaved and the people of Armenia butchered wholesale, would we escape either the risk or the responsibility? Those that deny the responsibility also belittle the risk. Europe is far away, they say—7000 miles distant from San Francisco, for example; the powers of the Entente will worry through somehow they assume—without knowledge; let the European nations settle their account with Germany and let us—these fools insist—proceed on our peaceful way, not without some supercilious regret that civilized peoples should have descended to such a depth of depravity. These political Pharisees and ignorant Scribes are now the enemies of the great cause to which the United States is committed, heart and soul, pacifist and jingo alike. Here we venture to interject a quotation from an article by Mr. Vernon Kellogg, in the current *Atlantic Monthly*: "I say it dispassionately, but with conviction: if I understand the German point of view, it is one that will never allow any land or people controlled by it to exist peacefully by the side of a people governed by our point of view." Mr. Kellogg is a lover of peace, a scholar by profession, a man eager to aid suffering humanity, as shown by his work with the American Relief Commission in Belgium and France. Again he says: "I have seen that side of the horror and waste and outrage of war which is worse than the side revealed on the battlefield. How, I hope for the end of all war! But I have come out believing that that cannot come until any people which has dedicated itself to the philosophy and practice of war as a means of human advancement is put into a position of impotence to indulge its belief at will. My conviction is that Germany is such a people, and that it can be put into this position only by the result of the war itself. It knows no other argument and it will accept no other decision." And to this we may add the statement made a few days ago by Mr. Robert Lansing, the Secretary of State: "If any of you have the idea that we are fighting

others' battle and not our own, the sooner he gets away from that idea the better it will be for him, the better it will be for all of us." It is the intention of Our Allies—no longer The Entente—to re-assert the public law and to save civilization from red ruin. We have many reasons for drawing the sword—plenty of them. We are fighting to avenge the American men, women, and children that have been assassinated on the high seas; we are fighting to redress the wrongs of the innocent Belgians; we are fighting to prevent the domination of the world by a cult that considers an international treaty "a scrap of paper," that believes "necessity knows no law," that asserts the submarine to be "the last word of kings"; we fight against a system of government that is without conscience and a mode of warfare that is without shame; we are fighting for our own safety, for the preservation of democracy, for the peace and liberty of the world.

## Oil Legislation Needed

How long would it take the Board of Directors of the United States Steel Corporation to decide on the re-opening of a closed but not exhausted iron mine if more ore were needed to supply the furnaces at Gary and if that mine were the only immediately available source of increased output? We believe that Judge Gary, with a war on hand that needed an accelerated production of steel billets, would see to it that a resolution authorizing the opening of that mine were put to vote and carried in about 15 minutes. We need oil for industry and for driving battleships; we shall be drawing down our last margin of ten million barrels in storage in the State of California in September 1918 unless the hopeless obstacle to development that exists because of the wholesale withdrawals of land may be removed by appropriate legislation. To be sure, the power to withdraw involves the power to restore, but it would mean a return to the evils of forced over-production on land that would instantly be located, and the locations pending could and would be forced to patent; in short, the intention of the Government when the withdrawals were made would be defeated, and this was mainly to regulate the output of the oil needed so as to preclude wasteful over-production and the ruination of large resources of oil by the flooding of productive strata through injudicious methods of drilling. Congress has trifled with the obligation it owes to hosts of oil-operators, actual and prospective, by failing through six years of talk to reach a subject of such vital national importance; in consequence we face a situation calling for 1,083,000 barrels of oil per month in excess of the production, with only 38,000,000 barrels in storage, and no addition to the available supply can be made. A committee of the Senate could ascertain at one sitting the best-digested thought of the country regarding an enabling act under which rational exploration and development of the oilfields could be undertaken without prejudice to public or private interests that would be one-tenth as dangerous as the

injury now inflicted on both through inaction. The Committee on Petroleum of the California State Council of Defense has just issued a report on the oil crisis that every citizen should read. It insists upon the need of instant action by the Government. Without it we shall find ourselves impotent; we shall be unable to maintain our manufacturing, our transportation, our naval activity. When will Congress act!

## The Nitrate Fizzle

Mobilization of the chemical industry of the country has been effected, according to a statement by Mr. W. H. Nichols, chairman of the Chemical Committee of the Council of National Defense. This is true so far as mobilization of the chemical manufacturers is concerned. It does not mean that the chemical resources of the nation are mobilized, because we are deficient in manufacturing capacity with which to utilize our enormous supplies of raw material. Moreover the Chemical Committee has not been given authority over special committees of the Government that are supposed to contribute toward the urgent needs of the moment. The most glaring example of failure to mobilize our chemical resources is shown in the absolute refusal to take advantage of the power conferred by an act of Congress for establishing a nitrogen-fixation plant in order that we might not remain dependent upon the Chilean nitrate deposits, which are available only by means of transportation across 700 miles of ocean. The law that authorized the construction of a Government nitrogen-fixation plant carried with it an appropriation of \$20,000,000 for the purpose. A Nitrate Committee was appointed the duty of which was supposed to be chiefly the selection of a site that would be so demonstrably superior to any other as to defeat the objections of the pork-barrel type of congressional representative. It is lamentable to record that the intent of this law was scuttled at the very beginning by a group of men distinguished in the chemical industry. Their reputation in the world of technology was not enough to command attention. At a time when Germany was erecting nitrogen-fixation plants of various types, and when similar works were being established in Sweden, the impression was created in this country that the fixation of nitrogen was still in an experimental stage. The details of the methods used abroad are known, however, to American chemists; they are men among us that are familiar with every modification of these methods as carried out in commercial practice. Nevertheless, the Government was expected to wait until we could put forward a series of independent tests. It was not enough to show how our preparations at a time when other nations were insisting that we take steps to meet what would be an existing impending conflict. An answer was then being urged on the ground of financial action in the spending of the public money, but no work toward mobilization is now possible for the nation of which that have

robbed this measure of its larger purpose. It indicates that malign influence is active at Washington. Mr. N. D. Baker, Secretary of War, issued a statement on July 16 in which he announced that a few small plants would be constructed at a cost of about \$4,000,000 for the fixation of nitrogen by a modification of processes previously known, but not involving the use of water-power. He added, "the committee is engaged in the making of further engineering studies, and the subject is temporarily closed to further discussion by localities and communities desiring to be considered as possible sites for the plants." The Secretary of War appears to overlook the fact that we are actually at war; yet the three governmental departments represented on the Nitrate Committee vainly undertake research upon modifications of tried processes instead of embarking on a course charted by others that have been making fixed nitrogen successfully abroad. It is well enough to blaze new trails, it would be eminently proper to expend \$4,000,000 in efforts to improve upon the older processes. The trouble is that these experiments are definitely intended to supersede other efforts to create plants to produce fixed nitrogen for an immediate emergency. The only things that will be accomplished will be to check our preparations for war and to endanger our supply of nitrate and for the manufacture of explosives. This action by the Nitrate Committee cannot be taken on the name of a true American. If the Government has become deaf to entreaty to hasten the construction of the nitrate plant authorized nearly a year ago, perhaps there be remain patriotic citizens with money enough to build the work. Secretary Baker's experiments are being made. It might be worth while to risk the possibility that some of the foreign methods would act as well on this continent and in our special atmosphere as they do in Europe. The arc process could be quite safely relied upon to behave reasonably well, even on the Pacific coast where a good deal of energy is still available at the summer months of some of the producers of hydro-electric power, especially if advantage be taken of the valleys between the peak-loads. The cyanamide process could be expected to give analogous results in the United States as those obtained in Canada and elsewhere. Some progressive men might undertake to utilize the Serpet process for making ammonia through the treatment of bauxite with producers, whereby purified alumina is obtained from the aluminum nitride produced in the furnace. This suggests the rationality of converting the relatively cheap fuel available near many of the American bauxite deposits into producers, from which this valuable nitrogen compound would be recoverable in connection with the refining of the bauxite for the manufacture of aluminum. Failure to secure departmental action because of faulty organization at least must have the excuse of good intentions to offer for this delay and the deliberate shunting of so important a project as the immediate domestic production of nitrogen in suitable form for making explosives was where so many of the War before us is not so easily explicable.

# DISCUSSION

*Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.*

## Patents

The Editor:

Sir—During the spring of last year you gave a good deal of space to a discussion of patents, to which I contributed the letter that you published on May 27, 1916. In your editorial of March 3, 1917, you published some statistics of the past year's work of the Patent Office that shows the fallacy of our present system. Frequent articles, letters, and editorials in recent issues have shown the impracticability of our patent laws, and have indicated the dangerous monopolies that can result, and the utter lack of reward to sundry meritorious pioneers.

The whole question of the patent law is becoming critical, and as I do not see any suggestions being put forward that offer a solution of the problem, I take the liberty of asking for space enough for a rather lengthy statement. The subject is too complex to be dismissed in a short letter.

As the present law fails so completely in meeting our economic and social needs, we can best base a proposed new law on scientific reasoning; and I am convinced that, as in the case of flotation, there will be much criss-cross of thought before we understand the position. One thing I stoutly maintain, and that is that the formulating of a new patent law, a mining law, or laws affecting engineering education, will be better handled by engineers than by lawyers, patent attorneys, or politicians, to all of whom human variance and distress are meat and drink.

The real difficulty is to postulate an objective, as in such an extremely technical case, the referendum of public opinion is impossible; and the interests of the rest of the relatively small groups directly affected, and having knowledge of the subject, are almost diametrically opposed. Incidentally the discussion in the columns of the MINING AND SCIENTIFIC PRESS is most appropriate, as I believe that this paper was originally founded to register improvements in invention, particularly with relation to mining and metallurgy.

An invention is a thing of generic form; the resulting machine is a thing of concrete form; the first may have value for a time, but, commercially considered, it soon ceases to have value, generally, from two causes, (1) the expiration of the patent and the ceasing of monopoly; and (2) the fact that at any moment, and surely ultimately, it will be superseded by better inventions; but nationally it always has value, as being the basis of subsequent progress. An invention in the end is more of a public and national acquisition than a personal one;

this is the real reason why it is never treated from the same legal perspective as real estate.

I believe that it will be best and most convenient not to give the ultimate and unrestricted power of monopoly to either of the interested parties, but to consider the inventions as of public utility, to be held in trust by the Government for the Nation. This then is a suggestion for an entirely new point of view, namely, that the Patent Law and the working of the Patent Office shall be based on the national ownership of patents. This is not to be confused with the national exploitation of patents. The inventor and the public would have the right to make, use, and sell, subject to license from, and the payment of royalty to, the Government. Half, or some suitable proportion of these royalties, would be distributed *pro rata* to the inventor or inventors, as also a subordinate amount of the royalties accruing from subsequent inventions or improvements developed from the parent idea. These royalties would be subject to certain general conditions to be described later.

The balance of the funds, which would be considerable, would pay for the running expenses of the Patent Office, so that registration could be made free. Funds would also be available for technical assistance and advice to the inventor, for research laboratories, publications, and other forms of special work, assistance, and reward, for meritorious workers by methods also to be described.

The Patent Office would be a much more important department of the Government than it is now, and would probably need representation by branch offices in all the important cities.

The fundamentals of this project may be summarized as follows:

(1) The act of applying for a patent would automatically assign the invention to the Nation, thus preventing personal ownership, but not interfering with commercial initiative in manufacture, sale, or use.

(2) The copying, manufacture, sale, or use of all designs or inventions, once declared novel or patentable, by the Patent Office, and for which a certificate has been issued, is to be subject to a royalty, said royalty to be payable only to the Government, and in amount and manner to be determined by the Patent Office. Such royalties should when possible be codified, and be based on a percentage at the sale-value; all questions regarding royalties to be settled by a Board of Commissioners of the Patent Office.

(3) Full protection for the inventors by a free, simple, and assisted means of registering creative ideas, in what-

ever department of art, science, mechanics, or general industry.

(4) Avoidance of all disputes and lawsuits, as to interference or infringement, by the Federal Government becoming the trustee for the national ownership of all patents, and simply adjusting the apportionment of reward to inventors by a distribution of a share of all royalties accruing to the Government. The share being in accord with the merit of the inventor's contribution, whether a basic idea, the fundamental of many others, or merely an improvement in the art.

(5) The cost of running the Patent Office to be paid out of the Government's share of royalties, instead of out of fees for registration. This would be a tax on success, whereas the present system is a tax on effort and enterprise.

(6) Practical assistance and stimulus for inventors, by the establishment of laboratories, work-shops, and test-plants, where, subject to proof of legitimate endeavor, merit, and capacity, the inventors could develop, test, and prove their ideas free of charge, and place them on exhibit, so that when meritorious they would get a chance of being brought to public use as soon as possible. See C. This work could be done on a generous scale as the amount of funds available would be so much greater than those accruing from the present system of fees.

(7) Great stimulus would be given to the inventor, by the ease of registration, by assistance, guidance, and technical suggestion from trained experts, by facilities for reference, research, and actual test, by opportunities to have their inventions demonstrated to prospective manufacturers, by freedom from the difficulties and legal expenses of protecting their ideas, and by the certainty of a moderate reward if their ideas were used and adopted. The certainty of a moderate reward would be a far greater stimulus to the average inventor than the chance of millions; and human consideration on the part of a common-sense Patent Office would be worth more yet.

(8) Protection of the manufacturing interests from undue monopoly would be obtained by the Patent Office placing the patents on the open market, so that all manufacturers could enter into competitive manufacture, subject to an equal royalty to the Government, of which the Government gives a share to the inventor or group of inventors, according to merit. When a basic idea has been developed until some time after the life of the patent, or when new discoveries, bring it within the utilitarian field, a special form of reward to be described and payable out of a special reserve fund would be provided. Evasion of royalties should be treated as a serious offence, such as the present evasion of Federal taxes. In every case the royalties should be moderate so that they would in no sense be an incubus on industry.

(9) The general public would be protected from the common practice of buying patents to prevent their competitive influence on other patents that have been already developed by large capitalistic groups. This

burying of useful inventions is detrimental to the interests of the general public.

(10) If it appeared that capital required protection or stimulus, as evidenced by those cases where, after throwing the patent open for competitive manufacture, no one comes forward to place it in public use, another procedure would be followed. If, after one year of open market, due application were made, either by the inventor or by parties representing manufacturers and capital, stating that the invention had merits, and that the parties were willing to place it on the market, or use it, provided a monopoly was granted to them, claiming that, as a considerable risk in capital outlay would have to be made to test and develop the idea, they could not undertake it without a monopoly, the Patent Office could then withdraw it from the open market. The patent would be offered for sale as a close monopoly, much the same as at present, with the difference that the term of the monopoly would be only for a part of the life of the patent, the remainder being thrown open to competitive manufacture as before. Royalties would be adjusted on a fixed scale, of which a certain proportion goes to the monopoly-holder who risks his capital, a certain proportion to the Government, which the Government again divides with the patentee. Monopoly patents not exercised would be withdrawn and again thrown open to competitive manufacture, sale, and use. No possible opportunity would be given for the deliberate suppression of invention useful to the general public, and done only for the purpose of accentuating monopolies that are already an incubus on society.

(11) The whole purpose of the Patent Office would be to encourage the registration of ideas, to reject worthless ones, to bring the apparently useful ones to the notice of the manufacturer and user, to reward the inventor of those that prove useful, or that are the parent of other useful inventions, to test and develop elementary ideas on new lines, to prevent monopoly of a class that would retard further useful development.

There is probably no such thing as an absolutely new idea, it is always the outcome or growth of some prior state of the art; all that the Patent Office has to determine is that the invention put forward is not in common use, and that as put forward and assembled it is reasonably novel; minor technical infringements are immaterial, so long as the actual result is a real improvement when applied to the art. There may even be cases when a research-worker deserves reward for developing to a utilitarian point, a process or art that is already known, or we might say the clarification of an art; for in many cases the cost of such experimental work, not to speak of moral and mental energy, would not, and often could not, be commercially undertaken, without the protection of a patent and the reward accruing therefrom.

What we want is to make life materially easier and better for the whole human race, and to stimulate, protect, and reward the persons that are contributing to that desirable end.

The Patent Office should be the go-between and ad-

juster; hence it should be the final arbiter as to the merits, patentability, and title to inventions.

(12) The result of such a programme would be that the Patent Attorney, as such, would automatically vanish. The Patent Office would assist the inventor in elucidating his ideas, not in formulating claims put forward only to block further development. Some compensation seems to be due to the patent attorney for the abolition of his office; no doubt a great many of them might be usefully absorbed as employees of the new department and its branches. There are many technical men in the profession whose services would be invaluable, especially when the temptation was removed of encouraging palpably worthless ideas as a source of profit from fees. But we must not forget that according to our postulate we are not proposing to legislate for the benefit of any one group, but to stimulate progress in invention that will be of the greatest good to the greatest number.

(13) To admit full liberty of personal initiative on the part of the inventor, and to guard against too much power and paternalism on the part of the Patent Office in the matter of the rejection of ideas, it will be well to have some class of registration provided to meet those cases where after the technical advisors of the Patent Office have returned an idea to the inventor, stating that it is novel but worthless, the inventor could still obtain a patent if he wished to do so. This and other similar problems could be met by having several classes of certificates issued, some of which may be suggested as follows:

A. Copyright, more or less as at present.

B. Trade-mark, also as at present.

C. Registration of minor ideas, details of mechanical ideas, or improvements in arts or processes. This would be termed a Minor Patent, and would not be subject to royalties, and could be freely adopted by the manufacturing public. The Patent Office would reserve a special fund out of its general income, for the purpose of giving rewards for these Minor Patents, the rewards to take the forms of certificates of merit, medals, and small cash payments. In some cases research scholarships, and even small life-pensions, could be granted for work under this head that had proved to be meritorious, as shown by its general adoption by the public.

D. Ideas that had novelty, and therefore were patentable, but which, on technical grounds, the experts of the Patent Office considered worthless, would be returned to the inventor with a report for his consideration. If the inventor still desired a patent, a second class of Registration Patent would be issued for a short term not to exceed ten years, subject to royalty.

E. Ideas that were evidently novel, and even possibly basic, and with merit, but that were undeveloped, would not be immediately patentable, but would receive a certificate of registration, giving the inventor certain rights of experiment, at the nearest research laboratory, and possibly some financial assistance from the special fund. The nature of the invention would not be published until

after it had been developed and proved, and fully patented. A time limit would be set for the inventor's experimental work, and his rights would be forfeited if he did not show due diligence in the prosecution of his research.

F. Inventions that had been developed and proved, and had been examined and passed by the expert advisor of the respective department of the Patent Office would be admissible and subject to full protection under the title of First Class Patents, which would be good for 20 years and subject to participation in royalties, and in some cases to monopoly rights; it would be unassailable in the courts, the Government guaranteeing its title to originality.

(14) The journal of the Patent Office would be different from the present publication. It would be divided under various industrial heads and ideas registered; and patents issued would be classified accordingly, so that readers could at once find the latest development in the art of any particular industry. There would also be intelligent criticisms and descriptions of the latest inventions, which would stimulate the technical press to copy and discuss. At present the inventor can get no publicity, the technical press seems to think it criminal to publish or discuss a new idea until it has been tried at some plant. How many failures at mills could be prevented by a little intelligent discussion regarding new machinery.

(15) The employees of the Patent Office should be well paid life-service appointees, subject to an examination as a branch of the Civil Service. There should be a strict rule that no employees could ever take out, or hold any interest in any patents, even after leaving the employ of the Patent Office.

The above gives at least a general scheme for a new law. If these suggestions, and those already put forward by other writers, are the means of starting a general discussion from all the interested groups, we shall soon get daylight on the subject.

## Notes on Flotation

The Editor:

Sir—I submit a few notes which may be of some assistance to the man who is undertaking practical flotation work for the first time with a machine of the Janney type. They may prove of more interest perhaps to the operator living in a locality where facilities for visiting a flotation-mill do not exist. I shall restrict myself to the consideration of a plant designed for the recovery of copper-sulphide ores. The theoretical side of flotation has been dealt with extensively in various issues of your paper, but I do not recollect having seen published any notes intended primarily for the novice.

The proportion of solid in the feed may vary between 20 and 30%. The specific gravity of the feed within these limits does not seem to have any definite influence

on the recovery, as with the same oil-mixture sometimes a better, sometimes a worse, extraction is made with the same pulp-density. With a thin feed a larger quantity of oil is necessary, and the quantity required diminishes as the specific gravity of the pulp increases till a point is reached where more oil is again necessary, for the froth now becomes so heavily coated with slime that an excess of oil must be used to cause the froth to flow over the lip of the cell. A further disadvantage of a thin feed is that the passage of the pulp through the machine is too rapid to permit of a high recovery.

The feed goes to 'rougher' cells, and the first question to be considered is the degree to which emulsification should be carried. In practice where there are two emulsifying-cells, should one of the emulsifying motors be stopped the froth-level falls almost immediately and more oil has to be added to the feed. The froth now becomes of lower grade and is lighter in color owing to carrying some slime. When the feed is comparatively rich in sulphides the color of the froth in two adjacent sections, one using two emulsifying-motors and the other only one, is practically the same; but if the feed should become poorer the difference in color at once manifests itself. This indicates the importance of sufficient emulsification.

As the 'rougher' cells are followed by cells in which the tailing is re-treated, the question naturally arises as to the extent to which recovery of the sulphide content of the feed should be made in these first cells. Let us consider the two extremes. If the froth on the 'roughers' be dark, a good deal of work is thrown on the secondary cells, and the ultimate recovery may be affected adversely. If the froth be kept very light in color by the use of an additional quantity of oil the recovery is higher, but it is made at the expense of the grade of concentrate, for a larger quantity of slime is carried over and the proper cleaning of the froth becomes correspondingly difficult.

The 'water-level' in the cells is best kept at two to three inches below the lip of the cell. The level should not be kept so high as to cause breaks in the froth-layer, for at such points the mineral burden is dropped; nor should it be so low that the froth collects in masses and overflows only in a sluggish manner. It must be borne in mind that it is through the agency of froth that the sulphides are recovered and hence a sufficient and uniform overflow is imperative in good practice. As the overflow of froth would be most rapid in the first cells, especially in the froth-cleaning machine, the distance between the top of the canvas and the lip of the cell is made greater at the feed than at the discharge end, so as to ensure a more even distribution of the oil in the machine and thereby to effect a cleaner separation.

The water-level has to be raised gradually from the feed to the discharge end of the machine, as the froth is more profuse in the first cells, becoming less abundant and more fragile in the direction of pulp-flow. This is effected by means of the gateway provided for each individual cell. It is found that a somewhat higher recovery

is made by 'slopping' in the end cells, that is, maintaining so high a level that the uprising air will throw over some of the pulp. This is permissible if the froth be again led to cleaning cells. The cleaned froth goes to a stock-tank from which it is distributed to the Dorr thickeners attached to the filter-plant. If the bubbles be tenacious and plentiful the froth will have to be broken down to prevent an overflow from the stock-tank. This may be done by jets of water or by the application of a vacuum; the latter method has not been found reliable in every instance. Possibly the application of heat may be of some use by causing an expansion of the enclosed air and a consequent rupture of the bubble-walls.

With respect to the volume of compressed air necessary, it is found that less air is required in the first than in the last cells. If too much air be used the bubbles burst and the froth-level sinks. To ascertain whether a low froth-level is due to the volume of air being used, the quickest method is to shut off the air for an instant and then to open the valve gradually until the best results are observed.

In summary, we may say that if the froth lies in heavily armored inert masses not enough oil or air is being employed, or the water-level is too low. If the froth consists of small bubbles that form in such profusion as to race down the sides of the cell, oil in great excess is being used. If the froth be light in color, the cause may be found in a slight excess of oil or air, a high water-level, or a pulp of too great a specific gravity. The extent to which the tailing from the roughers should be re-treated is entirely an economic question. The grade of concentrate will be determined by smelter requirements and transportation charges. The oil-mixture will depend upon the availability of the oils in the quantities demanded by the tonnage to be treated by flotation, upon the cost of the oils, and upon the recovery effected by their use.

The canvas on the air-pans should be changed when a large hole develops, for it is not possible to obtain a uniform or sufficient froth when the air rises through the pulp in strong local currents. In any plant treating large tonnages a certain amount of oversize is found at times in the flotation-feed. Where the air-pressure is between five and six pounds, this coarse material is prevented from lodging on the canvas. With air-pressures, however, of between two and three pounds the canvas has to be pounded occasionally. In any case it is best from time to time to wash the canvas, especially in the first cells, so as to remove any oversize or firmly adherent slime. Care should be taken, of course, that the stick used for pounding should neither have any sharp edges nor be wielded too lustily.

PAUL T. BRUHL.

McGill, Nevada, June 18.

WATER is absent from the petroleum-bearing Catskill sandstones of Pennsylvania and West Virginia, as shown by Frank Reeves in *Economic Geology*. These, and the Western Red-beds, are dry because of arid conditions prevailing when laid down.

THE MINE AND MILL OF THE MIAMI COPPER COMPANY

## Miami, Arizona: The Discovery—I

By T. A. RICKARD

The traveler that arrives by night, reaching the end of his journey in the dark, has the satisfaction of seeing his objective without any of the detraction due to approach. I arrived at Globe on a belated train and motored to Miami, six miles, after sunset, so that there remained nothing to recall from that last lap in the journey except the hand of hospitality, a steep hillside road, and then a smooth and level pavement, groups of serried lights that betokened big reduction works, and the bracing night-air of an arid region. In the morning a faint sulphurous odor indicated the nearness of a smelter. Stepping out-doors I saw Miami—at least that better part of the settlement that surrounds the offices and dwellings of the Miami Copper Company. Behind the main buildings were smaller red-roofed white houses and behind them spread a familiar Arizonan landscape—bare hillsides dotted with chaparral and paloverde, spaced with the sparing infrequency of the desert garden. The surface of the ground along the hillside showed reddish to the west and gray to the east, a distinct line of demarcation suggesting the contact between different rocks, and, having read something about the local geology, I guessed that the gray indicated the conglomerate, which covers and limits the ore-bearing schist, itself reddened by the oxidation of its pyrite. Near-by, and south, the dump of the No. 4 shaft showed crumbly red rock that resembled the discard from a mill. This easy disintegration of the country-rock must be, said I to myself, a factor in the success of the 'slicing' system—which bore no reference to breakfast, now cheerfully imminent. From over the hill came the muffled roar of a big mill, and, turning half-round, eastward, I saw the source of the sulphurous smoke, the big black

mass of the International smelter, silhouetted, like a super-dreadnaught ready for action, against the blue of the Apache mountains, dimmed by a morning mist and by the smoke of another smelter, that of the Old Do-

MAP OF ARIZONA

minion. The scene was eloquent of profitable activity and of human resourcefulness. Looking at the staff-quarters, the club-house, and other mitigations of life in this wilderness, I recognized how much progress had been made in the last three decades by mining companies in the effort to provide for the comfort of their employees, more particularly the technical staff. For examples of such provident forethought we owe something to the British companies formerly more numerous in the West than they are now. They may have gone too far, often building handsome houses for the management before they were assured of a persistently profitable enterprise, but they led the way in humane recognition of the vital necessity for taking proper care of the health and welfare of their people. With that kindly thought I proceeded up the hill, to breakfast.

Afterward, from the Tinkerville ridge, 200 yards west of No. 4 shaft, I saw something of the geology of the district and evidence also of the excavations being made below-ground. Underfoot were cracks that threatened an old boarding-house and that eventually must endanger the main shaft, the No. 4. These cracks come from subsidence above the stopes, such subsidence being a necessary factor in the success of the system of mining, as we shall see later. Thus the line of the subterranean orebodies is indicated by the surficial displacement due to the mining now in progress several hundred feet underground. The ore-belt follows a ridge of schist flanked on the south by granite. It is called the Schultz granite after a settler who owns a ranch on this terrain. Going north the schist loses its mineralized character. Knobs and combs of dark rock mark the remnants of comparatively recent dacitic lava-flows. On the Tinkerville ridge, where we are supposed to be standing observant, the rock underfoot is conglomerate—the Gila conglomerate—the fault-contact of which causes it to cap the ore-bearing schist at an angle of about 45°, and hinders prospecting south-eastward. This conglomerate contains fragments of schist, granite, and dacite, but the pieces are not wholly rounded; many of them are angular; the rock is the consolidation of miscellaneous detritus and might be labeled more accurately an 'agglomerate.'

In the company of J. Parke Channing (Columbia '83), the vice-president of the Miami company, and B. Britton Gottsberger (Columbia '95), the resident manager, I was shown the signs of ore that had led to the exploratory work preceding the discovery of enormous orebodies, now yielding 17,000,000 lb. of copper per month from two adjoining mines, the Miami and the Inspiration. The story of this great mining adventure is as follows:

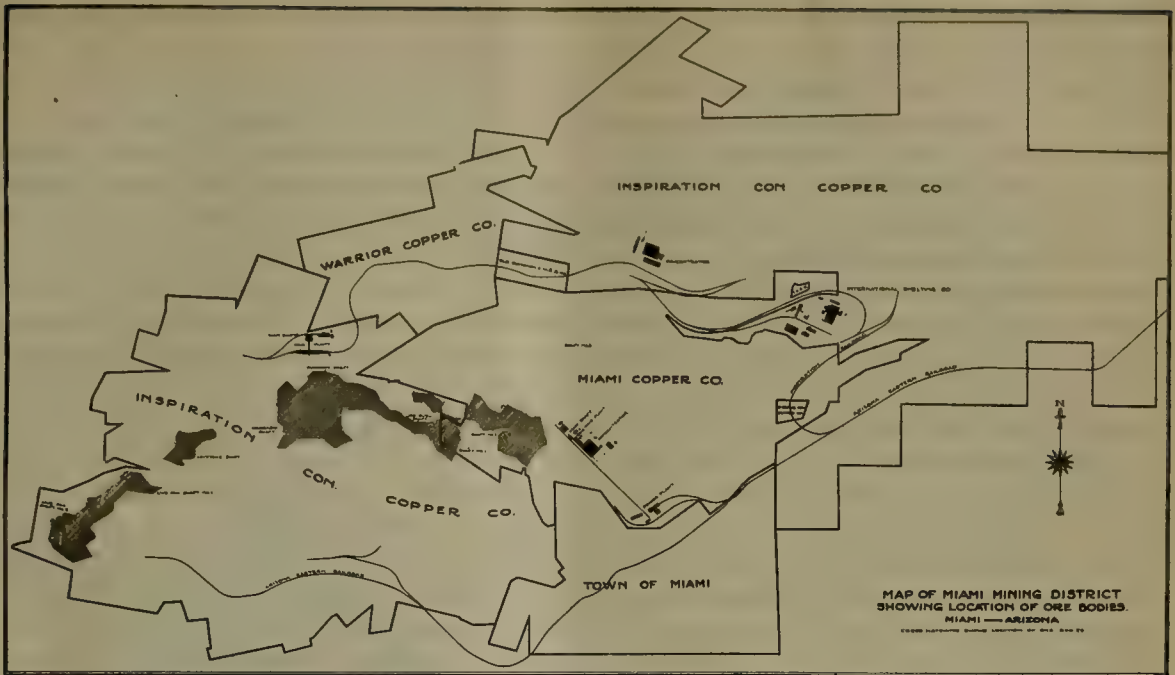

In November 1906 Mr. Channing was at Globe on a visit to the Old Dominion mine. On the third day of his visit, while at the Dominion hotel, he met Fred. C. Alsdorf, a graduated mining engineer (Ohio '92), whom he had known in Gilpin county, Colorado, in 1895. In the course of a friendly chat Mr. Alsdorf told Mr. Channing that he had been on a scouting expedition and that while engaged in this search he had run across a prom-

ising disseminated-copper deposit on ground about six miles west of Globe. He explained also that, having lived a number of years at Clifton, he knew the surficial signs of this type of deposit. Likewise Mr. Channing had his eyes trained to the same kind of indications, for he was familiar with the great 'porphyry-copper' mines at Bingham, he had examined the deposit of the Nevada Consolidated Copper Co. the year before, and he had brought to his examination of that mine the insight acquired by his visit to the Arizona Copper Co. at Clifton in 1897, at which time James Colquhoun was sending to the concentrator an ore that looked like burned lime with occasional specks of black chalcocite. Mr. Channing realized how Lake Superior mining methods and Montanan smelting practice could be applied to a large low-grade deposit of this character. In short, he was in a state of preparedness to appreciate the makings of a big copper enterprise based upon a large tonnage of disseminated chalcocite ore. A graduate of the Columbia School of Mines, a former assistant manager of the Calumet & Hecla, the consulting engineer and president of the Tennessee Copper Company, and the examiner of a number of famous mines in the West, Mr. Channing was ripe for the opportunity that Mr. Alsdorf put in his way.

They met on a Thursday. Mr. Alsdorf said that he had submitted a preliminary report by telegraph to some people at Colorado Springs, asking them to send their engineer to make an examination. On Saturday he told Mr. Channing that the people at Colorado Springs had telegraphed that they had no engineer available and that he was at liberty to dispose of the property as he saw fit. Thereupon he and Mr. Channing took horses and rode to what is now the Inspiration-Miami district.

Near the western edge of this mineralized area there was an adit—the Woodson tunnel—that had been driven in the course of extracting rich carbonate ore, and at its farther end this adit had penetrated low-grade material showing specks of chalcocite. Together these two engineers rode back over the ground, dismounting at intervals to examine the surface; at the eastern end of the mineralized ridge they came to the group of claims that Mr. Alsdorf had under bond and that now constitute the holdings of the Miami Copper Company. Mr. Channing examined the ground; then, recalling his experiences at Clifton, Bingham, and Ely, he told Mr. Alsdorf that he also considered the property worthy of exploration. The next day he interviewed the several claim-owners and had a talk with F. J. Elliott, an attorney at Globe, in whose name several of the options stood. These options called for cash payments such as were not justified by the condition of the property, which had only a few 10-ft. holes without a pound of ore visible. The meeting with the owners lasted until the small hours of the following morning, by which time Mr. Channing, representing the General Development Co., controlled by the Lewishorns, had taken an option to purchase the property for \$250,000, of which \$150,000 was to be paid in cash, and \$100,000 in the stock of a

\$2,000,000 corporation. The first payment, of \$50,000, was to be made in six months. Mr. Channing returned to New York and sent Louis A. Wright (Michigan '04) to make an examination of the prospective mine. The report of this engineer confirmed the opinion of Messrs. Alsdorf and Channing that there existed a good chance of uncovering a large deposit of disseminated copper. In December 1906 two shafts were started under the supervision of Mr. Alsdorf: one on the Captain claim, where there was a showing of carbonate ore, and one on the Red Rock claim, where the cap was so thoroughly leached that only a rare spot of green could be detected. However, the cap on the Red Rock impressed Mr. Channing because it was well silicified and showed residual iron, which was not in such excess as on the Red Spring claim farther north. Silicification accompanies the solution and removal of the soluble portions of the rock; an excessive coloration suggests that the downward migration of the copper had not kept pace with the erosion, preventing concentration at a lower level.

The two shafts were sunk simultaneously by the aid of gasoline-hoists. At a depth of 100 ft. the Captain shaft passed out of copper-stained silicious schist into rock showing specks of chalcocite, and 70 ft. deeper it penetrated the granite, which at this point contains the primary sulphide, chalcopyrite. The granite was cut again in a drift extended north-westward at the 150-ft. level, whereas a drift in the opposite direction struck leached schist within 100 ft. The shaft was sunk to 200 ft., and at that level a drift was driven 70 ft. south-east in granite showing pyrite and chalcopyrite. Later exploration has shown that if this shaft had been placed 200 ft. farther west it would have cut the Captain ore-body at a depth of less than 75 ft. The result was dis-

appointing. Meanwhile the Red Rock shaft was being sunk through leached cap-rock, and it was not until April, at a depth of 200 ft., that the shaft penetrated suddenly into the zone of secondary enrichment, the schist assaying 3% copper, as chalcocite. The shaft went through 50 ft. of this material; a level was started from the bottom; and at the end of May drifts had been extended 50 ft. each way to the four points of the compass. The showing was encouraging, so that in June the first payment was made. Mr. Channing went to Alaska, and on his return in October he found that the development had been so favorable that 1,000,000 tons of ore was assured. Just then came the panic of 1907, the local bank closed its doors on the day after the pay-roll checks had been issued, and Mr. Channing was under the necessity of paying the men with his personal checks upon a New York bank. Fortunately, the local bank got into good shape before long and there was no loss. By March 1908—fifteen months after the start—there was 2,000,000 tons of 3% ore assured; the shaft, then 710 ft. deep, had proved the vertical extent of the ore and most of the drifts—2518 ft. in aggregate length—were in good ground. Thereupon the Miami Copper Company was organized with a capital of 600,000 shares of \$5 each, a total of \$3,000,000. Inasmuch as this was a 50% increase on the capitalization specified under the option, the promoters (the General Development Co.) increased the number of shares going to the claim-owners, who then received \$150,000 worth of stock. By this time about \$100,000 had been spent in development, so that the total expenditure incurred in purchase and exploration was about \$400,000. Of the 600,000 shares authorized, 300,000 were delivered to the General Development Co. for having found the mine and developed it to that

stage. A block of 200,000 shares was sold at par in order to raise \$1,000,000 of working capital. As the mine underwent development it became evident that the million would not suffice, so later the 100,000 shares remaining in the treasury were sold at \$10 each, raising another million. In 1910 the capital was increased to 750,000 shares, and the extra 150,000 shares sold for \$2,500,000; thus altogether there was raised for development and equipment about \$4,500,000, in addition to the \$400,000 paid for purchase and preliminary development. It is interesting to note how much money it took to convert a promising prospect into a productive mine. The original concentrating-mill, designed by H. Kenyon Burch, was intended to treat 2000 tons per day, but it was so well arranged that its capacity has been successively increased to 4000 tons, 5000 tons, and by the end of the present year it will be treating 6000 tons of ore and making a recovery fully up to the original expectation. At the time of my visit the Miami shares were quoted at a price that gave the mine a valuation of \$30,000,000; it has paid already \$11,190,000 in dividends, a sum of \$1,700,000 has been put back into development and improvements, and on April 1, 1917, the company had quick assets amounting to \$7,600,000, of which \$2,000,000 was cash.

These facts tell a story so eloquent that no rhetorical confectionery is necessary. It shows how intelligent observation and scientific reasoning can be brought to bear even on that exploratory phase of mining which has seemed usually so haphazard. The sum of \$400,000 was risked to ascertain whether there was enough ore to make a profitable mine; after that point was passed, the further development above-ground merely emphasized the bigness of the orebodies and the success of the enterprise. The story of the Miami also suggests that the successful exploitation of an orebody may involve operations on so big a scale as to require the expenditure of sums of money that make the original purchase of the bare ground seem quite cheap; it indicates that a mining claim without the intelligent use of capital is only second-rate scenery. The Miami story also shows the camaraderie that exists between engineers of the best type, and the good faith that is kept between them, as also between them and the community. It is worthy of note that Mr. Alsdorf was retained to superintend the prospecting, and that Mr. Elliott's services were engaged as legal adviser, thus emphasizing the confidence prevailing between the principal parties to the business.

A few supplementary notes may be recorded. Before Mr. Channing came to Globe in November 1906, as mentioned, he had been to the Ray district, making an inspection of that mineralized area. The prospect of developing a profitable copper mine seemed to him unattractive, so he dropped the project and went to Globe. The people at Colorado Springs that did not think it worth while to send an engineer to examine Mr. Alsdorf's option were Charles M. MacNeill and Spencer Penrose, who backed D. C. Jackling in the big Utah enterprise and became associated with him in other copper-mining

ventures, among them the Ray, which Mr. Channing had 'turned down.' Thus Mr. Channing missed the Ray and Mr. Jackling missed the Miami, plus the Inspiration, but both have ample reason to be satisfied with their good luck. As to the evidence available to Mr. Channing, he showed me the Woodson tunnel, at the western or farther end of the mineralized area. This adit had penetrated into a zone of secondary enrichment, the white decomposed silicified schist showing specks and veinlets of chalcocite. In the Clipper tunnel, about 100 ft. up the slope, the oxidized ore appeared. Viewed from the standpoint of secondary enrichment such oxidation is not a good sign, for it suggests either that the leaching has not gone far enough, or that 'tertiary' action has oxidized the 'secondary' chalcocite. That is why the Red Rock was considered best; it had no green stains; on the contrary, the rock was silicified and contained not too much residual iron. The sinking of the Captain shaft close to the contact of the intrusive granite with the schist, and in rock that was stained green by malachite, was complimentary to the old ideas of copper geology, whereas the selection of the site for the second shaft, the Red Rock, was prompted by an understanding of that theory of secondary enrichment for which we are indebted to Emmons, Weed, and Winchell. The scientific prospector nowadays looks for silicification, not too much iron stain, and a mere trace of copper, just enough to indicate that originally the rock did contain copper, now leached and re-deposited below. The old-timer looked for green stains. On the dump of the Live Oak, one of the early prospects based upon oxidized ore, I saw pieces of comparatively unaltered schist exhibiting chalcocite alongside quartz stringers. Mr. Murphy<sup>1</sup> might have said of Miami that "the soins were moonificent; there was seriouscrite for Mudd, iron for Wright, silky for Channing, and the ox-hides of copper to indicate that it was not a tin mine, begorra." To use a gambling simile, Mr. Channing placed a chip on two numbers, and one of them was a winner. If, however, the Red Rock shaft had been 200 ft. farther west it would have penetrated some very poor stuff, so poor as to have caused an abandonment of the venture, the other shaft, the Captain, having penetrated low-grade primary mineral. To revert, the evidence of leaching at the surface, supplemented by the disclosure of chalcocite in the adit, sufficed to excite the logical expectation of finding, by sinking, orebodies of a size proportioned to the surficial area shown to have been affected by chemical solution and sub-aerial erosion. Thus advanced technical knowledge was applied to an old mining district.

Miami—the name is that of an Indian tribe formerly in Ohio and Indiana—was the scene of mining operations nearly 40 years ago. The early exploratory work done in this part of Arizona was stimulated by the richness of the Silver King mine, 19 miles south-west of Globe.

<sup>1</sup>See 'Mr. Murphy on Ore Deposits.' M. & S. P., August 22, 1908. Who would guess that this and other truly humorous articles were written by a person so deadly serious as the San Franciscan representative of Minerals Separation?

This discovery was made in 1874, at a time when the Apaches under Geronimo were still rampant in the region. The Silver King continued productive until 1884. Globe was selected as a distributing point on account of its good supply of water, obtained from the bed of Pinal creek. For a decade the surrounding district produced silver and gold, rather than copper. In 1883 there were 12 small mills in operation, extracting the precious metals,<sup>2</sup> but by 1887 the principal mines had been exhausted and were idle. In 1881 the Old Dominion company erected a small copper-furnace, about six miles nearly due west of Globe, where Miami now is, to treat oxidized copper ore found in the schist. It

THE MIAMI NO. 4 SHAFT

proved of no immediate consequence; so this pioneer smelter was moved to Globe, to treat the silicious copper ore produced by the Old Dominion mine. By 1886 there were six smelting-furnaces in the district, but they ceased work at the end of that year on account of the low price of copper, then quoted at 11 cents. In 1888 the Old Dominion company was re-organized, starting on a new and successful career, which has continued to this day. In 1895 the Black Warrior became prominent. The copper ore was found along a fault where it passed from the underlying schist into a remnant of dacite-tuff.<sup>3</sup> At that time the Black Copper, Keystone, and Live Oak were regarded as promising prospects, all of them working silicious copper ore in what is now the Miami belt. In the geological report by Mr. Ransome, dated 1903, it is written: "In the vicinity of Live Oak gulch the por-

phyritic facies of the Schultze granite has been much fissured and shattered, and is often conspicuously stained with carbonates and silicate of copper, while workable deposits of chrysocolla have been exploited on a small scale in the Live Oak and Keystone mines."

The green dumps of the Live Oak and Keystone claims, now part of the Inspiration property, serve to remind the visitor of the mining for oxidized copper that preceded the big-scale chalcocite developments of recent years, so little anticipated by the Government geologist. This oxidized ore was mainly the silicate, chrysocolla,<sup>4</sup> found in small veins traversing the granite.

At one time Phelps, Dodge & Co. controlled a large part of the district. In 1892 this firm purchased the United Globe mines, and shortly afterward their resident manager, Edward H. Cook, in their behalf, acquired a group of nearly a hundred claims covering the Miami area. In 1888 the Bigelow group had participated in the reorganization of the Old Dominion, but about 1903 individual members of the firm of Phelps, Dodge & Co., led by Charles Sumner Smith, obtained control of the Old Dominion also, although this property and the United Globe were operated separately until early in the current year. Phelps, Dodge & Co. held options in many parts of Arizona at the time when those claims west of Globe were cast aside and there was no reason to suspect that 2 or 3% copper ore could be exploited profitably, even if the existence of such ore under the oxidized cap had been surmised, which it was not. However, a little gossip is welcome once in a while.

Some day, when the big deposits of the Miami district have been worked out, we shall have the pleasure of reading a delicately worded obituary notice on this important district by some Government geologist. Meanwhile, the student should read Mr. Ransome's

early report, in which the outlines of the local geology are laid down clearly.

The Pinal schist, in which the large orebodies are found, is of pre-Cambrian age. This crystalline basement was invaded and penetrated by the Schultze granite relatively soon after the pre-Cambrian sediments had been deposited, the result being extreme metamorphism and faulting. Emerging from the sea, these ancient rocks underwent long-continued erosion. Then followed a subsidence, during which fresh sediment was deposited on the former land-surface. The alteration of subsidence and elevation was repeated many times. Each period covered a vast space of time. To paraphrase the language of a play-bill at the theatre, the curtain is lowered to mark the passage of a million years. Marine organisms laid down the substance of limestone. Crustal unrest was shown by faulting and by intrusions of

<sup>2</sup>Globe Folio, U. S. G. S., 1904. F. L. Ransome.

<sup>3</sup>"The Geology of the Globe Copper District." U. S. G. S. Prof. paper No. 12. F. L. Ransome. Page 156.

<sup>4</sup>Some of it is fine enough to be cut for jewelry, such as cuff-buttons. Locally it is called 'keystonite.'

diabase. Late in geologic time, at the beginning of the Tertiary period, there came extrusions of tuff and flows of dacitic lava, remnants of which are to be seen on the hills near Miami. Later still, in Quaternary time, the Gila conglomerate was accumulated so as to cover large parts of the district.

Turning to the economic geology: At the close of the Carboniferous period this district underwent a series of violent disturbances, culminating in fissuring, accompanied by intrusions of diabase. This was followed by cooling, settling, and then by more fracturing and fissuring; after which came further intrusions of magma. During one of the epochs of thermal activity, linked to igneous unrest, the primary copper-sulphide was precipitated in the granite and schist. Veins of copper ore cutting the diabase serve to indicate the relative age of that eruptive and the ore. The sulphide ore is older than the dacite. No sulphide ore has been found in dacite, but oxidized ore was stoped in dacitic tuff on the Montgomery claim of the Black Warrior group.<sup>5</sup>

Thus Mr. Ransome assigns the copper mineralization to late Mesozoic time. That probably was the period in which the process began, but it was not the period in which the orebodies were formed. It is not the original chalcopryrite distributed through the schist and granite that constitutes the mineralized rock valuable to man; the ore is a concentration caused by subsequent exchanges and migrations of metal, in operation during later geologic times. The fact that ore is found in the Tertiary tuff and in the detritus of a more recent day—a geologic yesterday—indicates that the ore-forming process has continued at work up to the very present. While the copper mineral is found in a pre-Cambrian schist, the copper concentrated to such degree as to be 'ore' is probably the product of Tertiary, or even Quaternary, activities. Hydro-thermal action, following eruptive action, caused copper-bearing solutions to rise toward the surface and precipitate their valuable contents as chalcopryrite, or copper pyrite, in the numerous fissures and shear-zones along which they found a passage. The diabase itself contains copper. The ore deposits now exploited represent enrichments made by the descent of copper solutions due to the leaching of the chalcopryrite in the overlying and eroded rock. The finding of chalcocite as a film covering the faces of fractures in chalcopryrite proves the secondary character of the chalcocite. The replacement of chalcopryrite by chalcocite, leaving a small residual core of the older mineral, is further evidence. As S. F. Emmons pointed out,<sup>6</sup> the occurrence of the chalcocite at the base of the oxidized zone, where carbonates and oxides give place to sulphides, is likewise significant. Indeed, the evidence obtained at Globe contributed to the formation of the theory of 'secondary enrichment' as put forward by Emmons. Mr. Ransome's report was written, under the guidance of Emmons, at the very time when this theory first saw the light. In the Old Dominion mine, the chalcocite was found first

just below the 400-ft. level and it was traced as deeply as 900 ft., where it is associated with unoxidized pyrite. On the other hand, kernels of chalcocite have been found surrounded by malachite, as in the Buffalo mine, and Mr. Ransome suggests that the change has taken place "in situ." This oxidation of chalcocite would nowadays be called 'tertiary,' namely, the result of alteration on a 'secondary' mineral, itself the product of the leaching of 'primary' chalcopryrite at a higher level. Whether the bulk of the oxidized ore is "indigenous," as Mr. Ransome says, that is, occupying the place of the original chalcopryrite, is a debatable point. It is likely that he would revise his opinion in the light of later evidence, particularly at Miami, where the concentration of chalcocite has taken place over a wide area and at a level well below the surficial zone of oxidation. In his brief references to this part of the district, Mr. Ransome says:

"In the case of the chrysocolla deposits of the Black Warrior, Geneva, and Black Copper mines, the ores occur as replacements of dacitic tuff, or possibly dacite in the last-named property, and their structure is such as to indicate strongly that they have been deposited directly in the tuff as the hydrous silicate of copper, and do not represent the alteration in place of former sulphides." He points to the "lack of iron oxide" as confirmation, as also "the fact that the ore is practically a single mineral rather than a mixture such as results from the oxidation of more or less pyritic ores." He concludes therefore that the chrysocolla ore is "exotic." As a hypothesis to explain such veins of silicate copper, he suggests the lateral flow of solutions that leached the copper from beds of tuff and from the surface of shattered schist upon which this tuff was deposited, the carbonate being changed to silicate "by the abundant silica present in the glassy tuff." This explanation seems reasonable. In regard to the chrysocolla of the Keystone and other veins in granite, Mr. Ransome was unable to speak confidently, for lack of evidence. He makes a remark that is highly interesting in the light of later developments: "The occurrence of some unoxidized pyrite in a stringer near the mouth of the lower tunnel [on the Keystone claim] indicates that if the chrysocolla is to give place to sulphides in depth, the point of change should not be far off. It is hoped that the mine will be successfully exploited to a sufficient depth to thoroughly expose this interesting deposit." As the children say in the familiar game, he was "very warm" just then; he was close to a discovery of more than academic interest. An observer coming 14 years later can appreciate the scientific humor of the position. There was plenty of iron oxide to be seen in the wake of surficial oxidation in this locality and there were wide-spread signs of chemical decomposition above the big bodies of chalcocitized rock now uncovered deeply underground. However, most of us can write last year's almanac better than next year's, and it is a safe surmise that the U. S. G. S. report on Globe furnished part of the suggestion that led the mining engineer of a later day to sink shafts in search of treasure.

# The Russian Crisis

By CHARLES JANIN

At the Editor's request I have prepared these notes describing conditions in Russia as I saw them during my recent visit to Petrograd by way of Vladivostok and Siberia.

**REVOLUTION.** The active cause of this was the lack of food in Petrograd. While there was plenty of food in outlying districts, the failure of those in charge of transportation to see that sufficient supplies were sent to the capital prompted riots and fanned to a flame the smoldering fires of discontent among the people. The revolution would have occurred later in any event: it was simply advanced by a few months, and when it did take place it was a spontaneous affair entirely confined to the working people, who were without definite aims other than to obtain food. The cossacks, who had been the main strength of the Government in putting down previous riots, were in sympathy with the people, for their stomachs too were empty. Many of the soldiers had been but recently recruited from the country, and were not in sympathy with the Government; on the other hand the police were 'loyal' to the Government. They had stored large supplies of food at their stations and could look with full belly on the growing discontent of the masses. The police were unable to cope with the situation. The crowd, emboldened by the friendly attitude of the soldiers, jostled the police on all sides. The cossacks would ride carefully through the insurgents, who would greet them with cheers. Voices could be heard saying "Our little brothers won't hurt us this time." Just when the real fighting began it is hard to say. A cossack officer killed a policeman who was attacking a peasant; a group of soldiers turned on the police that had been conferring with them; workmen attacked isolated police-officers in other places. In a short time fighting became general. Then soldiers shot the officers that were leading them to put down the trouble and joined the mob; other soldiers marching to join the revolutionists were halted and fired upon by patrols from their own regiment before the latter knew of the general movement. In a short time it was all over, except for fights with the police. These held their stations and the tops of buildings, where they had posted machine-guns in what they thought advantageous positions, neglecting to make sure they were really such, so that when the trouble began they found that they could not deflect their guns sufficiently to sweep the streets. A house-to-house hunt for police and arms ensued. At first the police were killed wherever found; some were brutally murdered by the crowd. A number of regimental officers became hysterical at the threatening mobs and foolishly fired their revolvers at them. They were

killed. During the first days of the revolution a party of soldiers coming down the Nevsky Prospect met other soldiers marching on a side street. Cheers for New Russia were exchanged and peace prevailed. Suddenly some enthusiast fired a gun. Intense excitement seized the whole party, who believed they were being attacked, and several hundred shots were fired in all directions at imaginary enemies. One curious American peeped

STREET-SCENE IN VLADIVOSTOK

out of his hotel-window to investigate the disturbance, but quickly withdrew when a bullet crashed through the glass above his head. Gradually order was restored by a provisional government; regimental officers and policemen were simply taken prisoners. The policing of the city was taken over by student organizations. For a few days after the revolution not an officer was to be seen on the streets. Then some of the old retired fellows appeared, and gradually the others were allowed freedom, but they had none of their former proud and arrogant bearing. Soldiers no longer saluted them when passing. The first ruling by the soldiers' deputies was, I believe, to abolish the salute. One rarely sees a soldier salute nowadays.

**THE PROVISIONAL GOVERNMENT** was formed hastily under Rodzianko and Miliukoff. These men were not leaders in the revolutionary outbreak and at first took no active part. They were accepted simply because the nation was without a head and the people turned to those who had offered strong opposition to the Czar's régime. No sooner was the Provisional Government appointed than the Radicals began to find fault with them and to agitate against them. Miliukoff was the first to feel the

disapproval of the masses because he announced that his Government would adhere to the treaties that the Czar's ministry had made with the Allies. This did not meet with popular approval. Demonstrations occurred in the streets against the new Government and against Muliukoff, against continuing the War, against the Allies; unfriendly crowds even gathered in front of the American embassy and American consulate. These were dispersed by 'loyal' regiments. The workmen had their own leaders, Socialists, such as the man Lenine, who was subsidized by the Germans. These men exercised considerable influence and won a numerous following: they are the main cause of the later disturbances. The Provisional Government should have put a quietus on Lenine's efforts at the start, but the members of this new administration did not seem to grasp the significance of this agitation, or else the situation grew beyond them and they were powerless to cope with it when they realized what was needed. They ruled only by sufferance of the Council of Workmen's and Soldiers' Deputies. Strong measures taken at the start would have saved much trouble, not only then but in time to come. The principles of the republic, however, forbade interference with free speech. The killing of Lenine was openly advocated on the streets, but his party defended him and threatened bloody reprisals if any violence was attempted. At times it seemed as though civil war or anarchy was inevitable, and that a complete collapse of the Army and Navy could not be averted. The workmen were growing considerably more reactionary, and clashes occurred in the streets between armed bands of workmen and soldiers. When shots were fired, we could see the crowds rushing this way and that, some to get away from danger, others to see what it was all about. I did not belong to the latter.

THE FUTURE of the country depends upon the attitude taken by the soldiers and the peasants. The greatest power at present in Russia is the Council of Workmen's and Soldiers' Deputies. The Army has the actual power, however, and needs only a great leader to control the whole situation. But this leader is not forthcoming. At first it was thought Brusiloff would be the man, but he, although a great tactician, evidently lacked the will or ambition to be a dictator, or perhaps conditions at the front were not favorable for such action on his part: instead, he resigned his position, and a leader does not gain prestige by such procedure. Kerensky was a great surprise, a 'dark horse,' so to speak; in the first burst of enthusiasm he had nearly the whole country with him. Then, partly through German influence, and partly through the anarchists—and there are many of this following in Russia—he lost some of his strength, which now he appears to have regained.

LABOR. The situation before the War was becoming serious, that is, there was a shortage of labor at the mines, and the importation of Mongolians and Koreans was advocated by engineers. Now the shortage is more acute. Austrian prisoners have been used with the permission of the former government to some extent; at

one mine known to me 4000 of them are employed. These men are well treated and fairly paid, so that they are much more contented with their lot than those not so occupied. On the railroad women are generally employed for section-work, and one rarely sees men in the fields, unless it be soldiers on leave or old men. The women and children plow the land. Wages throughout the country are much higher than formerly, and a further increase may be expected. Labor in general is asking for shorter hours, higher pay, and participation in profit. In places the workmen have made extravagant and outrageous demands. The 8-hour days is general now except where the workman has been strong enough to force a 6-hour day. At many properties the managers have been displaced, mostly without violence, and a committee elected from among the men to take charge. At some mining properties not only the workmen but the staff are demanding increased pay and shorter hours, and, in addition, arrears for the period since the War began. At other mines the management has deemed it wise to turn over all the profit to the workmen in order to preserve their plant, as the men have threatened to burn the buildings if their demands are not granted. In some instances it is reported that even this is not satisfactory to the workmen; they demand a portion of the invested capital. The cost of labor in general may be figured now at nearly double what it was before the Revolution and this even in districts where moderation prevails. With the increase in pay the efficiency of the individual has greatly diminished. In some cases industrial plants are closed down, as it is impossible to operate them at a profit. A complete collapse of industry was threatened shortly after the Revolution by the exorbitant demands of labor. The workmen were in command of the situation and all business had to be submitted to their committees for approval.

SOLDIERS. While the attitude of the soldiers for the most part was more favorable to the welfare of the new republic, there have been exceptions. Among the soldiers there were agitators similar to those in the workmen's parties, and some companies of soldiers paraded the streets with banners advocating peace, in opposition to the policy of the Provisional Government. There was a general lack of discipline among the different regiments; a number of desertions occurred from the armies at the front and from troops on their way to the front. The streets in Petrograd were crowded with soldiers, some marching to the front singing the Marseillaise, others returning from the trenches without leave. Many sold what clothes they could spare to the Jews. These deserters were on their way home to "get their share" of the land. Those to whom I talked said, "While we are fighting at the front, our brothers are getting all the best land." A few would add, "If it is necessary we will fight after we get the land, but why should we fight, we do not want indemnities or land from Germany." At the railway-stations these returning soldiers would crowd into the cars, occasionally putting civilian passengers off, and throwing their baggage out of the windows

after them. The newspapers of April 14 contained the following 'appeal':

"The Government has issued an appeal to the soldiers asking them to stop overcrowding trains, not to expel passengers provided with tickets, and not to present demands to the railway personnel. Many passenger carriages have been damaged owing to the overcrowding that has been going on during the past four weeks."

At the front the soldiers fraternized with the opposing troops, who had been ordered to encourage an exchange of courtesies. It was said that the Russian, in his great enthusiasm over the Revolution, believed that the millennium had arrived and that peace and goodwill would be universal. Whatever the idea, this fraternizing was encouraged by the Germans and it aided in the general disorganization and demoralization of the Russian troops. Officers whom I met despaired of ever seeing discipline restored; many resigned their commissions. Some of them told me that the situation was unbearable; one, a cossack colonel, just convalescent from his wounds, said he had returned to his regiment at the front, to the men with whom he had grown up, whom he commanded and led in battle, and that they would not recognize his authority. He said, "I want to go to America." The American and English embassies were besieged by officers of like mind, some wishing to volunteer as privates in the English army.

On the other hand, regiments of soldiers under non-commissioned officers, or committees elected by the men, retained their former officers and were instrumental in keeping order in the cities. It was regiments such as these that upheld the Provisional Government during the labor riots in Petrograd and really prevented anarchy. Outside of Petrograd order was much better maintained. The soldiers elected committees to take charge of affairs, and these committees in turn selected soldiers for policing the streets. On my trip through Siberia whenever soldiers tried to force their way into the cars, members of these committees would have the courage to order them off, and as the habit to obey was still instinctive, they got off. Some of these soldiers, after being put off the train, relieved their feelings by making faces at the passengers, but as they did not go beyond such facial exercises, we did not mind.

TRAVELING in Russia at present, of course, is far from pleasant. Trains are crowded to the utmost capacity with passengers and in addition soldiers endeavor to enter at nearly every station; sometimes the corridors of the carriages are filled with them, but on other trains the soldiers simply take possession of the vestibules. This condition obtained on the train on which I traveled, though personally I suffered no inconvenience from it. Most of the soldiers and sailors with whom I talked, through my interpreter, proved to be pleasant and agreeable. Food was scanty. Anyone who is obliged to travel in Siberia should provide himself with an ample lunch-basket, which may or may not be confiscated at the border.

Food. Transportation improved during the first few

weeks following the revolution, but food was becoming scarcer when I left Petrograd. A fair meal would cost from 7 to 10 rubles (a ruble being equal to 50 cents nominally, now 21 cents only) and this might or might not include bread; for three days or more no bread was purchasable. Those in the bread-line, after long waits, sometimes would receive a little less than a pound of black bread. This allowance was reduced to 12 ounces

A GROUP OF AUSTRIAN PRISONERS

daily per individual before I left. White bread was obtained with great difficulty at any time. The black bread is often unfit to eat; a mixed or gray bread is the kind generally furnished at the best restaurants, that is, when flour is plentiful. Those with influence or 'understanding' were able to get white flour; others purchased it through soldiers' wives. The soldiers seized freight-shipments coming into the city, and some, with

AUSTRIAN PRISONERS. A RUSSIAN GUARD ON EXTREME RIGHT

an eye to business, deputed their wives to sell the flour and sugar. In the high-class stores on the Nevsky 'luxuries' were still offered; prunes at \$1 per pound; canned goods at 8 to 10 times the American prices; chocolate at \$2 per pound (the further making of chocolate was prohibited in May); apples at a ruble apiece. Clothes were at fancy prices, ready-made suits cost from 250 to 300 rubles; shirts of the \$1.50 kind sold for 20 rubles, undershirts, socks, handkerchiefs, and neckties in the same proportion, and shoes—well, there was a riot on the Nevsky when a dealer announced the arrival of a

shipment at 80 rubles per pair, and crowds besieged the place as though it were a bargain-day. The shelves of most of the stores are bare. What a chance for a salesman in any line, and how they would be welcomed in Petrograd, if they could only guarantee deliveries! Delivery is dependent, of course, upon the transportation facilities.

**RAILROADS.** There is a shortage of locomotives, but the present rolling-stock of the trans-Siberian railroad is not used to one-third of its possible efficiency. Long lines of empty cars are seen on switches and on distant sidetracks. Freight-cars are sent loaded from Vladivostok, never to return. For those sent to the front some excuse may be made, but under energetic management more effective service could be obtained from the present stock. Lack of repair-shops and of mechanics is another feature. There is, strange to say, no assembly-shop for locomotives at Vladivostok, and any purchased in America must be first hauled on freight-cars to Irkutsk to be assembled. A large plant for assembling cars was built at Vladivostok. Thousands of cars were purchased in America, most of them of the small 20-ton type, but a number of large 60-ton cars were built by an American firm. I was told that this type was not popular, partly on account of the necessity for strengthening bridges and culverts, and partly because the workmen objected to filling so far behind the doors. Long before an American commission was mentioned, the Imperial Russian Government engaged an assistant traffic-manager of the Canadian Pacific Railway. This expert completed his investigations some weeks after the Revolution, and was reported to be much disgusted with the inefficiency shown; his report is in the hands of the American Railroad Commission. To illustrate the improvement possible under efficient management: An officer associated with the English transport service was engaged by the Czar's government to handle the Archangel muddle. After repeated discouragement in attempts to secure co-operation from officials, he was, through the effort of the English ambassador, given full control, and cleared the port in three months. Vladivostok has greater congestion, is much farther from terminals, and has much the same difficulties to face. The Ministry of Transportation in April expected to clear the congestion in eight months, but from personal observation I am in a position to guess that this is an optimistic estimate. At the time of my visit there were between 400,000 and 500,000 tons of freight at Vladivostok awaiting trans-Siberian shipment. Just what the American Railroad Commission can do, I do not know. It is a situation that requires infinite tact. If the workmen refuse to co-operate with their Russian managers it is a question whether they will welcome American methods and control. The Provisional Government stated that they welcomed the co-operation of America in new mining enterprises of every kind, and promised assistance in so far as it was in their power to render any. We were told that laws more favorable to mining activities were being formulated as rapidly as possible and every encourage-

ment would be afforded to capitalists willing to develop gold, zinc, lead, copper, and iron properties, with a view to bringing them rapidly to a productive stage.

**MINING.** At this time I do not know just what bonus has been fixed by the Government on the baser metals, but a ruling on prices to be paid on gold was made just before I left Petrograd. This was increased to 12 rubles per zolotnik as against 7.70 rubles before the Revolution and 5.50 in normal times. A zolotnik in gold is worth about \$2.83, and it can be seen therefore that the 12 rubles offsets the depreciation in Russian currency. Matters of titles, of taxation, of government ownership, and of leasing, and the treatment that will be given to existing companies holding large grants from the former government, are of vital concern to those interested in Russian mining. All the Crown lands and those belonging to members of the Czar's family have been declared confiscated for the public good. What policy will be applied to the leasing of this public land is not known; it is unreasonable to expect a new ministry struggling with matters more vital to devote much attention to details of this kind. I was told that a new director or perhaps a commission would be appointed to study the matter. Whatever the outcome of the inquiry, it will be limited to recommendations only. The policy to be adopted in the administration of public lands must be threshed out in open session of the Supreme Council; recommendations of ministers sufficiently socialistic will claim attention and be largely supported. The members of the ministry were favorably disposed toward securing foreign co-operation, and had liberal ideas in this direction. They could, however, only indulge in generalities, for they had no real power. Since then eight of the original ministers have been removed from office. There is a strong tendency to limit profits to a fixed percentage of the capital employed. This percentage varies with the individual; some, with no experience in such matters, contend that 6% is sufficient; others are more liberal. The companies now operating are much concerned over this phase, but hope that at least 15% profit will be permitted, with allowance for amortization of capital. The existing taxes, including war emergencies, now amount to 50% of the profit as shown on the books of one mining company. These are matters that must be studied in the interests of the prospective investor. Certainly, if profits are to be limited to 10% or thereabouts American capital will not be attracted to Russia.

**BUSINESS.** At the present time the situation is uncertain and unattractive to a conservative business man. Matters of government can only be worked out in time, and just now the vital need of the new republic is to unite against the Germans. This and the establishment of a stable government is the first consideration. If the Russians cannot do that unitedly or with sufficient force, it will not be a country to attract Americans. It will be Mexico over again.

The present financial condition is unfavorable; the ruble has dropped to 40% of its normal value. If rioting in Petrograd and other places continues, I shall expect

a further decline. If, on the other hand, a stable government is formed, the ruble will rise. A number of years must elapse before Russian finances are strength-

A GROUP OF SOLDIERS

ened to any great extent and care taken of external obligations, and it is only then that the ruble can go anywhere near par. There has been a vast increase in paper money during the War, for the Revolution was

SOLDIERS CROWDING ON TRAIN

not allowed to interfere with the printing press. I was informed through reliable sources that 1,000,000 rubles per hour was the amount gaily clicked off in notes. Such an increase in paper should be offset by a corresponding increase in gold reserves, and Russia's gold holdings do

not show any increase in this period. We shall have to finance Russia if we are to do business there.

There seems to be plenty of money in Petrograd among individuals. One hears of the enormous profits made through war contracts, and I was told that the directors of one of the banks each had 1,000,000 rubles extra dividends for the year. Porters and waiters seem to have an abundance of money, and fashionable *isvoschiks* in front of the hotels won't listen to less than a 5-ruble note for a short drive, where 30 kopecks (100 kopecks = 1 ruble) would have been the ruling price before the War. Paper money is universally used in Russia, even notes of one, two, three, and five kopecks are printed, though I never saw anything that could be bought with the smaller denominations, and one often saw these little bills blowing about the streets. They were probably thrown away by Americans who felt the time wasted spent in collecting enough to buy a newspaper. Stamps were used as money of 10, 15, and 20 kopeck denominations, but the ruble bill is quite a work of art. In Eastern Siberia, copper and silver coins made in Japan are used for smaller coins, and paper from 50 kopecks and over. When conditions become more nearly normal there will be splendid opportunities for American capital, engineers, and business men. A number of American firms have had representatives in Russia and the volume of business done in some instances has reached startling figures. On account of the conditions obtaining after the Revolution many Americans left Russia feeling that all business outside of that directly undertaken with the Government was impossible. The difficulty of obtaining transportation permits and of exchange, or as they call it in Russia "getting dollars," all militate against successful and satisfactory business. I believe that this is but a temporary condition, and that when resumption of business is permitted, an influx of American goods of every description is to be expected. American firms will do well to make a study of the conditions and needs of Russia as soon as possible, so as to place orders promptly to the best advantage when order is restored.

In order to work to the best advantage in Russia one should have a working knowledge of the language, and the language is very difficult to learn. It can be learned, however, with patience and application, as is proved by the success of the American and English engineers now in the country.

GERMAN motors captured during the War have shown superiority over those made in England and France, according to official statements from Washington. Exact duplicates made in shops of the Allies have not equalled them in endurance, and the difference is ascribed to characteristics of the steel that the French and English have not yet learned to reproduce. The U. S. Bureau of Standards is also working on the problem. The superiority is thought to be due to the method of retaining the so-called combined carbon in that form by methods that are chemical rather than mechanical or purely physical.

# Flotation—The Butte & Superior Case—II

## Brief for Defendant. The So-Called Critical Point

The contention that in reckoning the amount of oil which is referred to in the claims, account only should be taken of the oil which is attached to the metalliferous content of the concentrate, is not based on reason, or on anything in the specifications or claims. It is contradicted by everything therein. Claim 1, for example (which is typical), describes the process as consisting in "mixing the powdered ore with water, adding a small proportion of oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of 1% on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth," etc. Clearly what is described and claimed here is the use of a fraction of 1% of oil on the ore *in the mixture which is to be agitated to produce the froth*. Neither the specifications nor the claims make any reference to the amount of oil which attaches itself to the metalliferous content of the concentrate. The only reference in the specifications to the oil attached to the froth is the suggestion that the froth may be "treated with a dilute solution of acetic alkali, which removes the oleic acid in the form of soap."

Mr. Kenyon, in his oral argument, put this contention in another way; but in a way which amounts to precisely the same thing. After saying that we must consider as oil in the process only the oil which is attached to the metalliferous content of the concentrate, he said that from the total amount of oil used must be subtracted all the oil which goes off with the tailing; all the oil which is absorbed in the gangue of the concentrate; all the oil which is dissolved in water, etc. This is only saying in a roundabout way that the only oil which is to be counted as the "fraction of 1%" referred to in the claims is the oil which is attached to the metalliferous content of the concentrate, because when all these things are subtracted there remains only the oil which is attached to the metalliferous content of the concentrate. We have already shown that the specification and claims directly contradict this contention, because the fraction of 1% of oil which is mentioned in them is the oil which forms part of the mixture which is to be agitated to produce the froth. It is not the oil which is attached to the metalliferous content of the concentrate when the process is completed.

If the fraction of 1% of oil in the ore referred to in the claims is limited to the oil which is attached to the concentrate, then defendant's practice is still further away from the proportions specified in the claims, for Defendant's Exhibit 158 shows that the percentage of oil in the concentrate, when it uses more than 20 lb. of oil per ton of ore, is as much as 1.86% to 2.09%.

The contention that only a fraction of 1% of the oil used by defendant is effective, the balance being inert

and not to be reckoned as oil in the process is contradicted by the proofs.

Defendant has used various mixtures of oils. The mixture used by it during the joint run on April 29, 1917, which may be taken as typical, was, in round numbers, composed of 24% pine-oil, 65% fuel-oil, which is a petroleum, and 11% kerosene. Since fuel-oil and kerosene differ only in specific gravity, both being petroleum, we may simplify the formula by saying that the oil was composed of 24% pine-oil and 76% petroleum, or substantially one part vegetable oil to three parts petroleum. The amount of mixture used was 26 lb. per short ton of ore, that is, 1.3% of oil on the ore.

On behalf of complainants it is contended that petroleum is inert in the process, and should be neglected in determining the percentage of oil on the ore, within the meaning of the claims of the patent in suit. The suggestion is that petroleum was used only as a diluent to increase the bulk of oil without taking any active part in the process of the patent. This contention raises the question as to what is the "oily liquid" referred to in the claims. Does it include, or does it exclude, *mineral oils*, as the petroleum is?

In the specifications the "oily liquid" of the claims is defined as "oils, fatty acids, or other substances which have a preferential affinity for metalliferous matter over gangue." The specification then refers to the Cattermole patent No. 777,273 as describing the use of the same "oily substances" in larger proportions. Turning to that patent we find it states:

"The 'oil' used may be animal, vegetable, or mineral oil or mixtures of these or such coal or wood tar products or other substances which exercise, like oils, a preferential physical affinity for metallic mineral matter as distinguished from gangue."

Further on the specifications of the patent in suit say:

"The proportion of mineral which floats in the form of froth varies considerably with different ores and with different oily substances, and before utilizing the facts above mentioned in the concentration of any particular ore a simple preliminary test is necessary to determine which oily substance yields the proportion of froth or scum desired."

When we come to the claims we find that they define the oil as "an oily liquid having a preferential affinity for metalliferous matter." Hence we see that any liquid having, like oil, a preferential affinity for metalliferous matter over gangue is included within the term "oily liquid" in the claim. Since there is no dispute concerning the fact that petroleum has such preferential affinity, there can be no question but that they are in-

cluded within the term "oily liquid" contained in the claims.

The fact is, the practice of using a mixture of vegetable oil and petroleum is not peculiar to defendant, nor is it peculiar to a process in which oil is used in quantity above 1% on the ore. On the other hand, it is a practice which is in common use by those who use quantities below one-half of 1% on the ore, and who are *operating as licensees under the patent in suit*. Thus complainants' licensee, the Braden Copper Company, uses a mixture of 1 lb. American wood-tar oil to 3 lb. of Texas oil per ton of ore. At that place, therefore, where one-fifth of 1% of oil on ore is used, the mixture of oils used is precisely like that used by defendant, to wit, one part vegetable oil to three parts petroleum. Again, complainants' licensees at the Consolidated Arizona mine use between 2 and 3 lb. of oil per ton of ore, about one-half of it being Carolina turpentine, and the other half fuel-oil and stove-oil, both of which are petroleum. In this place, therefore, where about one-tenth of 1% of oil on the ore is used, the mixture of oils used is one part vegetable oil and one part petroleum.

Furthermore, as hereinafter pointed out, the non-licensees in this country, before they adopted the use of oil in quantity above 1% on the ore, used a mixture containing petroleum as one of its components. This was true of the Utah Copper Company at its Magna plant, and also at its Arthur plant; it was true of the Chino Copper Company; and it was true of the Ray Consolidated Company.

So, as we have said, the practice of defendant in using a mixture of vegetable oil and petroleum is not peculiar to it, or to the use of quantities of oil above 1% of the weight of ore.

That petroleum is not, as contended on behalf of complainants, inert in the process, is clearly demonstrated by the mill operations at the Arthur plant of the Utah Copper Company, records of which appear in Defendant's Exhibit 31. In one run the oil used was 20.33 lb. per ton, it being a mixture composed of 89% of what complainants' witnesses call inactive oils, that is, petroleum (30% Jones fuel-oil and 59% smelter fuel-oil) and 11% of what they call active oils (10% American creosote and 1% Yaryan pine-oil). In this run the extraction was 98.4%, and the tailing carried 0.076% copper. The actual amount of so-called inactive oil used per ton was therefore (being 89% of 20.33 lb.) 18.1 lb.; and the actual amount of so-called active oil used per ton was therefore (being 11% of 20.33 lb.) 2.23 lb. In another run substantially the same amount of so-called inactive oil was used *alone* (17.84 lb. of a mixture of the same petroleum, namely, smelter-fuel and Jones fuel, in the same proportions). In this case the extraction was 95.06% and the tailing carried 0.306% copper. In another run substantially the same amount of so-called active oil was used *alone* (1.97 lb. of a mixture of the same so-called active oils, that is, American creosote and Yaryan pine, in the same proportions). In this case the extraction was 85.72%, and the tailing carried 0.81% copper. These

determinations are not contradicted or questioned, and they prove that petroleum-oil used in this process is by no means inactive or inert. It is, indeed, quite as active and quite as efficient in producing the desired results as is the so-called active oil. Indeed, it will be observed that the petroleum when used alone gave higher extraction than did the so-called active oils when used alone. The highest extraction, however, was attained when they were used together in a mixture as defendant uses them.

So it is proved that it is the common practice of those licensed under the patent in suit, and others using less than one-half of 1% of oil on the ore, to use petroleum mixed with other oils in the practice of the process, and it is proved that the petroleum used is active as an oil—not inactive like milk or sawdust, as Mr. Kenyon said in argument—in effecting the concentration which is the purpose of the process.

Complainants' witnesses intimate that there is something peculiar about defendant's ore—that it contains an undefined amount of an undefined material, which Greininger called "gangue-slime" and which Chapman called "clay-gangue"—which makes it possible for defendant to use above 1% of oil—the inference sought to be deduced from this being that but for the presence of the so-called "gangue-slime" it would be impossible to practice the process with more oil than given in the examples of the patent, namely, under one-half of 1%. This testimony is mere speculation and inference, and *being adduced in rebuttal* it could not be replied to directly. It has been, however, sufficiently replied to indirectly by the proofs in the record showing that oil in excess of 1% is being regularly used at other mills than that of the defendant, where there is no suggestion that the ore contains any "gangue-slime" (whatever that may mean). The use of oil in excess of 1% on the ore has been, since the decision of the Supreme Court in the Hyde case, regularly used at the Magna mill of the Utah Copper Company, as testified to by Conrads; at the Arthur plant of the same company, as testified to by T. A. Janney; by the Chino Copper Company, as testified to by Wicks, and by the Ray Consolidated Company, as testified to by Engelman. In each case the mill-records of the plants, both before and after the use of oil above 1% on the ore was adopted as the regular mill-practice, were produced. The facts established by this testimony, in brief, are these:

At the Magna plant of the Utah Copper Company the change from below 1% to above 1% of oil on the ore was made on December 25, 1916. Before the change was made, the smallest quantity of oil used was in the month of March, 1915, when the average was 1.25 lb. per ton; and the largest quantity was used in the month of April, 1916, when the average was 5.37 lb. per ton. Before the change, a mixture of various oils, including petroleum, was used. In August, 1915, they used a mixture of Barrett creosote, Barrett No. 4, Jones oil, pine-oil, and an oil called No. 642, which is a reconstructed pine-oil. In August, 1916, they used a mixture of Jones oil, creosote, and waste oil. In December, 1916, before the change was

made, they used a mixture of Jones oil and creosote. After the change was made they used a mixture of Jones oil and Yaryan pine-oil. Defendant's Exhibits 35 and 36 give a complete statement of the mill-operation before and after the adoption of the use of larger amounts of oil than 1% on the ore. Exhibit 35, which gives averages for the entire period before the adoption of 1% of oil, compared with Exhibit 36, which gives averages for the entire period after the adoption of 1% of oil, show that the extraction before the change was 97.461% and after the change was 98.161%. They show that the copper in the concentrate before the change was 30.294%, and after the change it was 28.458%.

Defendant's Exhibit 38 gives a record of experiments made with varying amounts of a given mixture of oil while other conditions were kept constant.

At the Arthur plant of the Utah Copper Company the change from below 1% to above 1% of oil on the ore was made December 21, 1916. A tabulation of the results before and after the change is contained in Defendant's Exhibit 30. Before the change, an average of 3.76 lb. of oil per ton of ore was used, and after the change an average of 21.98 lb. of oil per ton was used. Before the change, the tailings averaged 0.361% of copper; after the change, they averaged 0.238% of copper. Before the change, the recovery was 96.57%; after the change, it was 96.60%. Both before and after the change they used mixtures containing petroleum oil as one of their ingredients.

At this plant a series of 13 tests, which were full-mill operations, were made using in all the 13 tests a mixture which was made of 89% petroleum (smelter fuel-oil and Jones oil), 10% creosote, and 1% Yaryan pine-oil. In these tests the quantity of mixture used varied from 6.87 to 96.46 lb. per ton of ore. As the amount of oil was increased from the lower limits, the recovery increased until 25.50 lb. of oil per ton were used. Using oil in larger quantities than 25.50 lb. per ton of ore, and up to 96.46 lb. per ton of ore, still gave excellent results (96.39% recovery), although the tailings carried a little more copper, to wit, 2.272%.

At the mill of the Chino Copper Company the permanent change from below 1% to above 1% of oil on the ore was made December 21, 1916, although they had for three days in November, 1916, used as much as 237 lb. of oil per ton of ore. Before the change, they used a mixture of creosote (Barrett No. 4) and petroleum (Jones oil), and since the change they have been using the same mixture, but with the proportions changed from 90% Barrett and 10% Jones oil to 10% Barrett and 90% Jones oil. The tailing-loss of copper averaged, before the change, 48%; and after the change, 32%. The average recovery before the change was 95.528%; and after the change, 96.936%. After the change the average amount of oil used was 22.18 lb. per ton of ore.

In direct contradiction of the theory of complainants' witnesses that petroleum is an inactive oil and plays no part in the production of foam, Wicks describes what happened one day in the mill in the regular course of

milling operations when the supply of petroleum was unintentionally shut off. He says the foam immediately disappeared, and no recoveries were obtained until the supply of petroleum was turned on again. At that time they were using 32.27 lb. of oil per ton of ore. See also testimony of Punchon as to the effect of suspending feed of petroleum at the Arthur plant.

At the mill of the Ray Consolidated Copper Company the change from below 1% to above 1% of oil on the ore was made the middle of January, 1917. A tabulation of the results before and after the change is contained in Defendant's Exhibit 44. Before the change they used a mixture of creosote (Barrett No. 4) and petroleum (fuel-oil), and since the change they have been using the same mixture, but with the proportions changed from 75% Barrett and 25% fuel-oil to 10% Barrett and 90% fuel-oil. Before the change the quantity of oil varied from 3.22 to 5.28 lb. per ton of ore. Since the change it has varied from 18.77 to 21.19 lb. per ton of ore. The average extraction before the change varied from 92.94 to 94.69% in different years; and since the change it has been 95.42%. The average copper in the tailings before the change varied from 0.617 to 0.375% in different years; and since the change it has been 4.12%. At this mill also experiments were made to determine the results of keeping the mixture of oil constant, and varying only the quantity used, which experiments showed that with the mixture now employed inferior results were obtained when a diminished quantity of oil on the ore is used.

So we see it is not anything peculiar about defendant's ore—the alleged presence of something nebulously called "clay-gangue," but not identified by any analyses, although complainants' experts had plenty of defendant's ore to analyze, and by which to prove its constituents, if they had seen fit to do so—which enables the defendant to use more than 1% of oil on the ore, because it is proved that at other mills, where the ore is not the same, amounts of oil in excess of 1% are being commercially and continuously used with satisfactory metallurgical results.

EXCESS-PROFITS TAX, as fixed by the final Senate committee-vote, increasing the maximum graduated tax on excess-profits of corporations from 40 to 50%, makes it necessary to revise previous estimates as to the extent of leading corporations to be affected. Under the new tax the old flat 8% tax is repealed and also the 12% tax on munitions exports. The following rates are substituted, based on the excess of current profits over normal pre-war profits; not in excess of 15% of the normal profits, 12%; in excess of 15 and not of 25%, 16%; in excess of 25 and not of 50%, 20%; in excess of 50 and not of 75%, 25%; in excess of 75 and not of 100%, 30%; in excess of 100 and not of 150%, 35%; in excess of 150 and not of 200%, 40%; in excess of 200 and not of 250%, 45%; in excess of 250%, 50%. This would result, for example, in collecting \$30 per share of common stock from the United States Steel Corporation.

## Californian Committee on Petroleum

\*The extent to which industries of national importance depend on Californian oil is shown by a pamphlet just issued by the California State Council of Defense. The fuel-oil from Californian wells operates the Panama Canal; the greater part of the steam-railroads of Washington, Oregon, California, Nevada, Utah, Arizona, and New Mexico; the steamship lines along the Pacific Coast from Mexico to Alaska and across the ocean to Hawaii; the gas-plants of California, Oregon, Washington, Nevada, Arizona, and Hawaii; the mines and smelters of California, Nevada, and Arizona; the cement-works and sugar-refineries of California; and it serves a substantial portion of the manufacturing, industrial, and agricultural enterprises of the Pacific Coast States, as well as the fuel supplying the requirements of the United States Navy and Army in the West. The products of Californian petroleum, such as kerosene, gasoline, distillates, lubricants, and road-oils meet the requirements of Arizona, California, Nevada, Oregon, Washington, Alaska, and Hawaii. Californian kerosene is shipped in enormous quantities to China, Japan, India, and Australia, and to the western coast of Central and South America, while the distillates and lubricants are sold in nearly every important State in the Union, and also in England, Canada, and Australia.

The total oil in storage in California on June 1, 1917, is reported to have been slightly in excess of 38,000,000 barrels. A portion of the crude oil in storage cannot be utilized because it is situated below the outlets of tanks and reservoirs, or is being used for the operation of pipelines or for other reasons. Of the total stocks on June 1, not in excess of 32,000,000 bbl. was available for use. Of this amount 12,000,000 bbl. was refining oil, and would yield approximately 7,000,000 bbl. of residuum; furthermore there was available from crude-oil stocks approximately 27,000,000 bbl. for fuel. The present excess of consumption over production amounts to about 1,083,000 bbl. per month. If that continues, the entire available storage of Californian fuel-oil will be exhausted by June 1, 1919. If a margin of safety of 10,000,000 bbl. of fuel-oil is maintained, that margin would be reached by September 20, 1918. The field-losses of petroleum have been almost entirely eliminated and the amount of oil used in drilling and pumping has been reduced by substituting natural gas and electric power. The use of fuel-oil cannot be entirely eliminated. The refineries are working on improved processes of refining; a proportionally larger amount of gasoline and lubricants is also being secured. The surplus of kerosene is being exported to the Orient, Australia, Central and South America.

Mexican petroleum was substituted early in 1917 for Californian petroleum. The amount was approximately

2,750,000 bbl. annually, heretofore sold by the Union Oil Co. in Chile. A considerable portion of the remaining 3,000,000 bbl. of Californian fuel-oil sold in 1916 on the west coast of Central and South America, including the Panama Canal, can likewise be saved by the substitution of Mexican petroleum. By reason principally of transportation difficulties, Mexican petroleum will not be available during the War as a further substitute for more than 3% of Californian petroleum. Coal cannot be substituted for Californian fuel-oil to any important extent during the War because of difficulties in the production and transportation of coal. Approximately 1,000,000 bbl. of Californian fuel-oil will be saved in the North-West next year by the substitution of coal by the Oregon Short Line and by other industries. The Los Angeles & Salt Lake railroad and the Western Pacific railroad will use coal produced partly in the Rocky Mountain States. The Southern Pacific and the Santa Fe can also gradually turn to coal on those portions of their systems that are in proximity to the coalfields. Powdered coal has been successfully used in cement plants, stationary boilers or power-plants, and in metallurgical furnaces. One cement plant in the North-West has recently converted its plant from fuel-oil to powdered coal, saving 84,000 bbl. annually. Hydro-electric energy has already been substituted to a considerable extent in industrial and agricultural uses, but the difficulty in securing copper and other materials and the disturbance of existing industrial conditions are such that large savings of fuel-oil by the substitution of hydro-electric energy cannot be anticipated during the War. We conclude that some further saving of Californian fuel-oil is possible by elimination of losses and by substitution of other forms of fuel or power, but that no large saving can be effected without serious impairment of the efficiency of the transportation systems and industries of the Pacific Coast. The increased production should amount to more than 30,000 bbl. per day, and such increased production cannot reasonably be expected before June 1, 1918. Each difficulty standing in the way of prompt and substantial increased production must be quickly solved to forestall a serious industrial crisis.

In our opinion, the only way to meet the situation, in view of existing conditions, is to have the Federal Government call upon the manufacturers of oil-well supplies to devote a sufficient part of the capacity of their plants toward supplying the requirements of oil-producers in California and other parts of the United States to meet their needs, and to direct the railroads to transport such supplies promptly.

Of the most desirable undrilled lands, approximately 70% is involved in litigation with the Federal Government. Nearly one-half of the best undrilled proved petroleum lands of the State are claimed by the Kern Trading & Oil Co., the fuel-oil bureau of the Southern Pacific Co., under patents heretofore issued to the Southern Pacific Co. Of the remaining lands in litigation, a part of the most productive undrilled land is in posses-

\*Abstract: Report of Conclusions and Recommendations by the Committee on Petroleum of the California State Council of Defense.

sion of Howard M. Payne, Federal receiver. The desirable Buena Vista Hills lands are practically embraced in Naval Reserve No. 2. A considerable area, however, of presumably productive undrilled but proved land, which in our judgment should be promptly and intensively drilled, is the Sunset field and in the east Coalinga field. The larger portion of these lands is claimed by the Kern Trading & Oil Co. A portion, particularly in the Sunset field, is in the possession of the Federal receiver. These latter should be promptly drilled. A review of the situation shows that the present emergency cannot be met without the assistance of the Federal Government. We desire, however, to emphasize the fact that a considerable portion of the proved productive territory, hitherto undrilled, lies outside of the naval reserves; that the further development of most of this land has been stopped by litigation with the Federal Government; that the policy of the Federal Government which has resulted in the creation of Naval Reserves No. 1 and 2 can have no possible application to these lands which are not claimed or needed for the Navy, and that with the help of the Federal Government substantially increased production can be secured from these lands. Unless the Federal Government can bring about radical changes in the supply of drilling material, the transportation of petroleum, and the development of the land, an increased production of over 30,000 bbl. per day, which in our judgment is necessary, cannot be secured without additional drilling in Naval Reserve No. 2.

We respectfully submit the following recommendations:

1. That every reasonable effort be made to increase the production of Californian petroleum promptly, and to this end additional drilling should be undertaken on the lands where the largest production can be developed in the least time, with the smallest expenditure of material and labor.

2. That every effort be made to conserve the supply of Californian petroleum by the diminution of field losses, the higher use of petroleum and its products, and the substitution of other forms of fuel or power.

3. That the facts with reference to the Californian petroleum situation be presented to the President, and that the Federal Government be urged to render assistance consistent with the public interest.

4. That the attention of the Federal Government be drawn to the advisability of directing the manufacturers of oil-well supplies to set aside sufficient capacity in their plants for the production of oil-well casing, drill-stems, wire-cables, and other material to supply the reasonable requirements of California.

5. That the attention of the Federal Government be drawn to the advisability of exempting from service in the armed forces of the nation all skilled workmen employed in the petroleum industry.

6. That the Federal Government be requested, in those instances in which Californian petroleum-lands now in litigation with the Federal Government are not

in the hands of the Federal receiver, to consent, through the Department of Justice, to stipulations under which the claimants will be permitted to drill such lands intensively, under engagement to protect the Government in its needed supply if it win the suits.

7. That the Federal Government be requested, in those instances in which Californian petroleum-lands now in litigation with the Federal Government are in possession of the Federal receiver, to take appropriate proceedings, through the Department of Justice, so that the receiver may be directed to proceed at once to drill intensively such lands as are presumptively productive, and particularly the lands which are likely to suffer from the infiltration of water unless soon drilled. Further Congressional legislation may be needed for this purpose.

8. That the Federal Government be requested to enact promptly the necessary legislation by which such lands in the public domain as the Federal Government may consider consistent with public interest may be opened to petroleum development on terms just and reasonable both to the Federal Government and to such persons as may proceed in good faith to the exploration and development of petroleum lands. We suggest that the area of the lands in each instance be sufficiently large to permit efficient operation.

GAS-FIRES are so obstinate that wells are usually left to burn until the flow of gas ceases. A new method was adopted recently by William Guerin of the New York Fire Department, who was summoned to Monroe, Louisiana, to try to extinguish a fire from a well flowing 44,000,000 cu. ft. per diem under a pressure of 1500 lb. per sq. in. The gas being salable at 2c. per 1000 feet the loss was at the rate of \$880 per day. In the course of months this would represent an enormous waste. Mr. Guerin was telegraphed for and he applied a method that promises to be generally utilized in similar cases. There was water available and pumps with which to develop pressure. Two fire streams were employed, the nozzles being brought close to the well, the firemen meanwhile protected by sheet-iron shields. The streams were played upon the gas-flow so that they met in the gas below the point at which combustion was possible, that is, where the pressure was so great as to maintain a velocity that would extinguish flame. The streams were then gradually elevated until their meeting place was at the base of the flame; the streams were then flattened out so as to make a horizontal fan; next the flames were wiped off by rapidly raising the fan formed by the meeting streams. The fire was extinguished in five minutes.

THE PRESIDIO SILVER MINE, in Texas, was in continuous operation during the first six months of 1917, and silver mining was also carried on during that period in the Van Horn and Sierra Blanca districts. Several shipments of copper ore were made from deposits in the 'Red Beds' of Foard and Knox counties. The result was a small output of copper, lead, and zinc; but a production of silver for the six months of 340,000 ounces.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## TORONTO, ONTARIO

PRODUCTION OF STEEL IN CANADA BEING LARGELY INCREASED.—

ELECTRIC STEEL-PLANT IN OPERATION.—COAL SHORTAGE GREATLY RELIEVED.—PORCUPINE OPERATING AT NEARLY NORMAL CONDITION.

The great scarcity and high price of steel, owing to War requirements, has given a great stimulus to the steel industry. Many new companies are being formed, and the existing plants are arranging for large extensions. President Mark Workman, of the Dominion Steel Corporation, states that all departments of the Sydney plant are operating to full capacity, and that good progress is being made with the additions and improvements now under construction at a cost of several million dollars. A new blast-furnace is expected to be in operation in the course of two or three months, which should increase the output by at least 35,000 tons yearly. A battery of 60 new coke-ovens is being built, which will be ready for operation during the winter, and a second battery of the same size will be completed in the course of a year. The Steel Company of Canada, the principal works of which are at Hamilton, Ontario, is seeking to provide its own coal and ore reserves. Acting in co-operation with large American interests, it is investing in coal and iron-ore properties situated in the Eastern States, from which its supplies will be drawn in future. Its plans for expansion include the construction of a large coke-producing plant on its Hamilton property with a capacity of 800 to 900 tons per day, work on which will be commenced promptly. Under present labor conditions, it is not expected to be completed in less than 20 months. The steel-plant of the British Forgings Ltd., of Toronto, which will be operated by electric process, using scrap-steel as raw material, is understood to be nearing completion, but as it is primarily a military enterprise, under the direction of the Imperial Munitions Board, there is a good deal of reticence as to its operations. It has 10 electrical furnaces with an aggregate capacity of from 300 to 400 tons per day at least, one of which has gone into steady operation. It is believed to be the largest electrical steel-plant in the world, and when working at full capacity will require 22,000 hp. and employ 3000 men.

The coal situation appears somewhat less threatening than earlier in the season, when fears of a serious famine prevailed. The appointment of C. A. Magrath as Canadian Fuel Controller has had a good effect. The transportation problem is being grappled with by Sir Henry Drayton, head of the Railway Commission, with a view to expediting deliveries, and the services of H. P. McCue, of Pittsburg, a leading transportation expert have been engaged to facilitate the filling of contracts, and prompt forwarding of shipments. Mr. Magrath has issued a statement urging consumers of coal to lay in their supplies as early as possible, and exercise strict economy, as, unless deliveries during the open season can be speeded up, a very heavy load will be thrown on the railways in the winter.

The Mines Branch of the Canadian Department of Mines estimates the total production of coal in Canada during the first quarter of 1917 at 3,590,991 tons, the rate of production being apparently less than the average in British Columbia and Nova Scotia, but greater in New Brunswick, Saskatchewan, and Alberta. Exports during the quarter were 501,570 tons and imports of coal 3,921,824 tons, as against exports of 501,570 tons, and imports of 4,002,892 tons during the correspond-

ing three months of 1916. Work has been resumed at the Crows Nest Pass and other mines of Alberta and British Columbia, under the orders of W. H. Armstrong, the commissioner appointed by the Government, under the War Measure Act, but there is a great shortage of labor, many of the miners having obtained other employment during the strike. As a result of the large increase in wages secured by the men, coal prices at the mines will be increased approximately 75c. to \$1 per ton.

Conditions at Porcupine show improvement, and now that the labor difficulties have been settled, many miners are coming in and finding employment. The McIntyre during June treated 14,455 tons of ore with a production of \$141,208, the mill-head running \$10.24 per ton. Production has been steadily maintained despite unfavorable conditions during the past six months. The drift at the 1000-ft. level is now in Jupiter ground, where the vein has widened to 55 ft. of a high milling-grade. The exploration of the Dome Extension property, undertaken by the Dome Mines, has been so delayed by insufficient working force that it is considered probable that the Dome will ask for the three months extension of their option, to which they are entitled. The option falls due on October 15. Hollinger Consolidated is pushing development, and has cut a new vein carrying free gold, and showing a high average gold content at the 425-ft. level of No. 10 shaft. The underground workings are being centralized, so as to make all the orebodies opened up readily accessible to the central shaft.

At the Kirkland Lake the shaft is being put down from the 600 to the 700-ft. level. It is estimated that the ore in sight amounts to about 50,000 tons, averaging from \$9 to \$10 per ton. Plans have been prepared for the installation of a ball-mill with a daily capacity of 150 tons. A water-seam has been cut at the depth of 165 ft. on the Elliott-Kirkland, which has caused the suspension of underground work pending the installation of steam equipment. Excavations for the foundation of the cyanide mill at the Lake Shore mine have been started. The recently discovered orebody at the 200-ft. level has widened to 40 ft. with ore of good milling grade over half that width. The Tough Oakes is as yet the only dividend-paying mine at Kirkland Lake, and has returned to shareholders a total of \$391,125.

The price of silver having reached 80c. per oz., the Cobalt miners receive an additional bonus of 25c. per day, so long as this figure is maintained. The silver-mining industry was never more active here, though production is declining in volume as the grade of ore treated steadily grows lower. More men are employed in the mines than ever before, the total approximating 3000, as compared with 2600 a year ago. It is estimated that production for 1917 will probably be about 19,000,000 oz., as compared with 21,500,000 in 1916, though the value will be considerably higher.

The two dividends of 15c. per share recently declared by the Kerr Lake Mining Co., payable August 10, was equally divided, one-half going to the Red Cross and the remainder to the Army and Navy branch of the Y. M. C. A.

Six of the furnaces of the Grand Forks smelter of Granby Consolidated have been blown-in with the receipt of fuel from Crow's Nest Pass Coal Co. Two sections are still idle. The Grand Forks plant was closed-down in April, when the company supplying fuel was shut tight by strike. Granby has a financial interest in the Crow's Nest Pass Coal Company.

## MAYER, ARIZONA

THE BINGHAMPTON COPPER MINE A NEW PRODUCER.—THE DEVELOPMENT EXTENDING AND A NEW SHAFT TO BE SUNK.—FLOTATION IN SUCCESSFUL OPERATION.

The Arizona Binghampton copper mine is five miles east of Mayer, in Yavapai county. It is an old property that has been in course of development for some time, the money for the work having been furnished by W. H. Reynolds, of New York. The company is incorporated with 340,000 shares at \$5. In May 80,000 shares was advertised and much of it was taken by officers and stockholders of the United Verde and the United Verde Extension, at Jerome. Those men have made suggestions as to the method of development. There are three miles of underground workings, and judging by the reports of mining men who have examined the property, there is but a small amount of the work done that does not count. It was the similarity of the formation to that of the Jerome district that induced some of the officials and stockholders of the Jerome mines to become interested. The ore is chalcoppyrite with some iron pyrite and tetrahedrite, disseminated in the Yavapai schist. Some of the stopes are 20 ft. wide and

BINGHAMPTON MILL NEAR MAYER

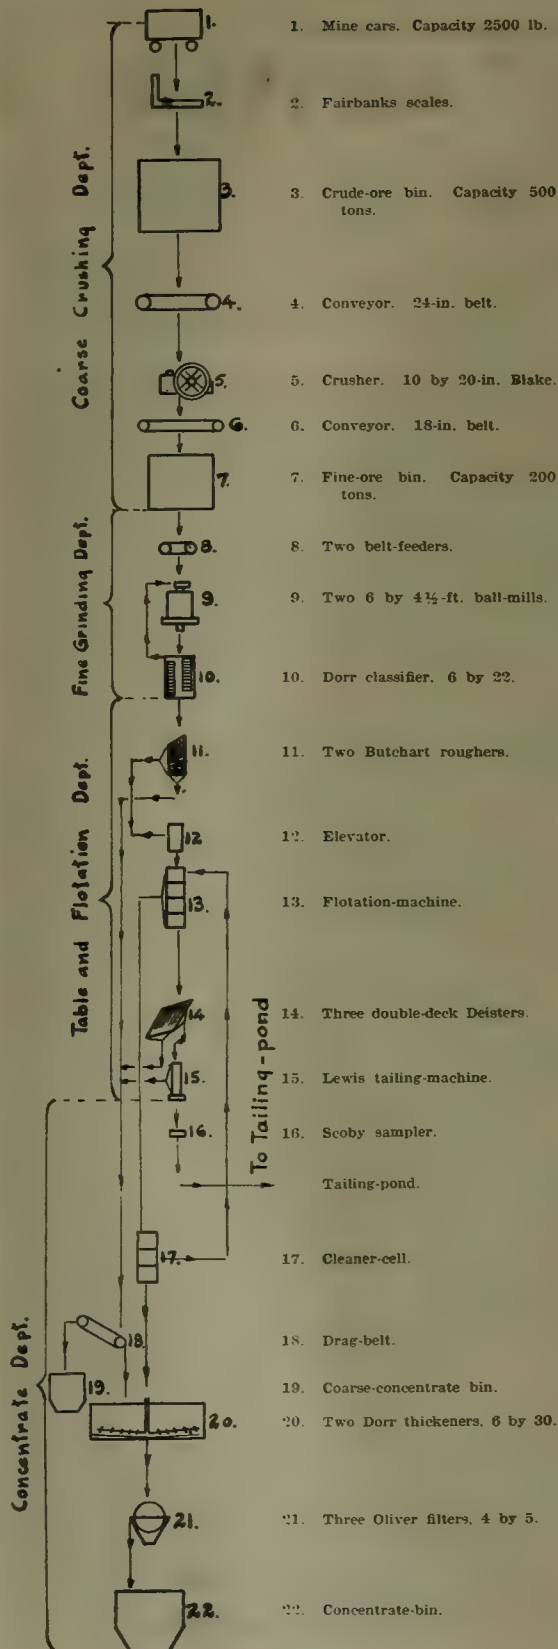

from 100 to 120 ft. long. On the 400-ft. level there is a stope from which a car of ore is shipped daily, running from 13 to 14% copper.

On the 600-ft. level, in the past few days, ore has been found in four shoots that are extensions of orebodies on the 400-ft. level. One-fifth of the output of the mine is coming from the 600-ft. level from the new development work. The nearest deep mine is the Blue Bell, 9 miles south-west, which has developed orebodies 40 ft. wide at the 1000-ft. level.

On August 24, of last year, a flotation mill of 100 tons capacity was started upon the property. The first day's run showed a recovery of 95%, but this has been lowered since for economic reasons to 85 or 90%. The concentrate runs about 20% copper. The mill was built after the plans of the Inspiration mill, designed by H. Kenyon Burch, and built under the supervision of C. B. Clyne.

The mill has exceeded the estimated capacity practically every day since it started. The output for May was approximately 300,000 lb. of copper which netted the company \$38,000. The mill has been doubled in capacity, and the new unit will be in operation in a few days with a daily capacity of 250 to 300 tons, which will give an output of about 500,000 lb. of copper monthly. There will be added to this a regular tonnage of high-grade ore, that at present is one car per day. This will be increased as the mine is developed.

The ore is hauled by contract from the mine to the mill, 1200 ft., in trains of 4 to 6 cars drawn by a mule. The ore is dumped from the ore-cars into the coarse-ore bin and broken to pass an 8-in. grizzly. The coarse-ore bin has a capacity of 500 tons. The ore is drawn from this bin onto a slow-moving

belt-conveyor which can be used as a picking-belt if desired, for sorting out either shipping-ore or waste. This conveyor dumps onto a 2-in. grizzly, the oversize going to a 10 by 20-in. Blake crusher which crushes to 3 inches. The crusher product and grizzly undersize are carried by a conveyor to the fine-ore bin of 200 tons capacity. The ore is then delivered by belt-feeders to two ball-mills which grind in closed circuit, with a 6 by 22-ft. Dorr classifier. The overflow originally went direct to the flotation machine, but later, when a marked increase in the value of the ore occurred, the much lower ratio of concentration justified the installation of tables ahead of the flotation machine, to remove as much coarse concentrate as possible, as a large tonnage which did not require fine grinding was put through the mill. The table concentrate is de-watered by a drag-belt. The coarse material then goes to the concentrate-bin and the overflow to the Dorr thickeners.

The flotation machine is of the Inspiration type. The rougher concentrate is re-treated in a cleaner, the reject from which returns to the rougher for re-treatment. Diaphragm-pumps are used for handling the cleaner reject and rougher concentrate. The reject from the flotation machine is treated by double-decked Deister tables. The table tailing is run through a Lewis tailing-machine and from that to the tailing-pond, where it is impounded and the water returned to the mill. The flotation concentrate is thickened in Dorr thickeners and dried by Oliver filters to about 12% moisture.

The concentrate is hauled by teams and motor-trucks to the railroad at Mayer, from which point it is shipped to the Consolidated Arizona smelter at Humboldt. The high-grade ore is shipped to the same place.

This mine is in the centre of a mineral district extending several miles in all directions. The Copper Queen has a mine adjoining and parallel on the east which has developed sufficient ore to warrant the erection of a 100-ton flotation mill which will be of the same design as the Binghamton mill. Work on its construction is to begin within 60 days. There are at least 20 properties in various stages of development within a radius of two miles. Half a mile south of the Binghamton mine is the Barbara property, a promising group that is under bond and lease to mining men from Bisbee.

### LEADVILLE, COLORADO

ALL THE MINES OF LEADVILLE DISTRICT ARE IDLE AND NEARLY 2000 MEN ARE OUT.—PUMPING AT THE MAIN DRAINAGE PLANTS CONTINUES.—TEXT OF STATEMENT ISSUED BY THE OPERATORS.

A complete tie-up in the mines of the Leadville district has resulted from the strike called Saturday morning, July 21, at 7 o'clock by the Cloud City Miners' Union No. 33 of the International Union of Mine, Mill, and Smelter Workers. All union and non-union men walked out leaving only a few managers, superintendents, foremen, and other salaried employees of the companies to operate the pumps. It is estimated that normally there are 1950 men employed in and around the mines. Of these the union claims 900 as members, the remaining 1050 being non-union. There were 103 operating shafts in the district prior to the strike, and of these 57 were producing. The total output for June was 65,700 tons, or approximately 2190 tons per day. A few small lessees continue to operate, though in each case the men at work are interested in the enterprise, but these lessees are producing only a small tonnage so that the output of the district is practically stopped.

Pumping at the big draining centres of the district, the Penrose, Harvard, Wolfstone, Greenback, and Yak tunnel, continues with crews of volunteers and salaried men at the pumps. The operators state that unless something unforeseen happens they will be able to continue pumping indefinitely although one or two properties are very short handed at present.

Union men picketed the roads leading to the mines on the

first day of the strike, cautioning those who passed from going to work. Aside from this, they have manifested no outward interest in the situation, and their leaders have declared that they will simply remain quiet and await developments.

Both sides are apparently disappointed in the result of the strike call. The operators believed that their non-union employees would not respond to the call of the union; and the union authorities were confident that their call would so cripple the mines that the pumps would be shut-down and the mines flooded, which they believed would greatly hasten a settlement. As it is, the opposing forces have come to a deadlock, and it appears that it is now only a question of which side can hold out the longer. The operators state that rather than give in to the organization they will allow the mines to close completely.

Old-timers in the district who witnessed the strike of 1896, declare that the present situation is similar in every way to the beginning of the disastrous trouble of 20 years ago. Quiet will undoubtedly continue until the miners become fretful over their inactivity, short of money, and rapidly getting into debt. Then it is expected there will be disorder that may lead to fatalities.

Just what the outcome will be is problematical. It is generally understood that the majority of the men have very little in the way of reserve funds to go on, and that they soon will find themselves confronted by a serious alternative—go to work or starve. Already many men have left the district seeking employment in other camps, but the general unrest through the mining centres of the West makes the assurance of a job out of the question. The union will probably receive benefits from the organization as long as the funds last, but the non-union men will be thrown upon their own resources.

The failure of the government mediators, George W. Musser and Verner Z. Reed, to bring about a settlement between the union and the operators has caused some to charge the mine owners with the responsibility for the strike. At the Denver conferences, the union agreed to compromise their demands of \$1 per day increase and accept 50 cents. The operators refused to consider this offer, and practically refused to give attention to anything except an offer from the Government to take over the mines.

In reply to assertions that have been made concerning their stand in the matter, the operators have issued the following statement:

"The present deplorable state of affairs in this district results from a long continued effort on the part of imported agitators to organize the miners of Lake county, and was precipitated by a demand of the Miners' Union upon the operators for a flat increase of \$1 per day to the present existing wage scale.

"The union has had some success in recruiting members here but is not considered as representing the majority of the miners employed. The fact that the Leadville operators have refused to deal with the union has been deliberately misconstrued to imply that they will not meet with their men. It might be well to again state that the managers are at all times willing to confer with their own employees and are always anxious to adjust any differences which may arise.

"It will be remembered that the State Industrial Commission, acting upon the solicitation and representations made to it by the local union, recently came to the district, made a thorough investigation of the working conditions, and conducted an open hearing, at which all questions pertaining to the existing state of the mining industry here were fully presented and considered in comparison with conditions governing operations in other metal-mining districts of the State.

"The crux of the report handed down by the Commission on May 29, was that an adequate wage was being paid; and since that time there has been no material change in the conditions passed on. Despite the fact that the union originally appealed to the Commission; it promptly proceeded to repudiate the

findings of the commissioners and made a demand on the operators for the \$1 per day increase. Owing to the source of the demand, it was ignored, whereupon followed the decision of the union to strike.

"Attempts at arbitration have brought no good results because the arbitrators were appointed at the instigation of the labor leaders, and when granted a conference by representatives of the operators, immediately, and without first giving the operators a chance to be heard or to define their position, presented a previously arranged basis for settlement which could not, in all good faith, be accepted by the latter, having in mind the best interests of the miners as well as the owners of the properties. There can be no fair or just arbitration of any question unless both sides have some choice in the selection of the arbiters and a full and thorough investigation of all conditions effecting the issue be conducted, before a decision is arrived at.

"The operators fully realize that this strike, involving loss of work to a large number of men, and the suspension of operations which sustain an important community, is a very serious matter, and they have persistently attempted to prevent it by all fair and reasonable means.

"The manner in which this strike was called, by discouraging pumpmen from remaining at their duties, with the evident intention of abandoning the pumps and permitting the workings to become flooded, shows clearly the pernicious influence behind this movement. Should it become impossible to keep the pumps in operation on the various large drainage enterprises now under way here, it will surely result in a disaster from which Leadville may never fully recover. Such a course is certainly not pursued in the interest of the miners themselves nor of the community at large.

"The demand for \$1 per day increase is of course absolutely unreasonable. The mining industry here, in its present state, simply cannot afford to pay such wages. If the demand be persisted in, it will unquestionably result in forcing a complete shut-down of all the mines."

The Arkansas Valley plant of the American Smelting & Refining Co., employing 850 men and handling 25,000 tons of ore monthly, continues to operate as usual. It is stated that there is sufficient ore in stock at the plant to supply it for two months.

The plant of the Western Zinc Oxide Co. employing 50 men and handling 1500 tons per month is also running normally.

### SILVER CITY, NEW MEXICO

LARGE SHIPMENT OF MANGANESE FROM SILVER CITY.—RICH GOLD ORE AT PINOS ALTOS.—A NEW MILL FOR PINOS ALTOS.—CHINO RAISES WAGES AND MAKING EXTENSIONS OF PLANT.—OPERATIONS IN BURRO MOUNTAINS.

Three to four cars of manganese ore is being shipped daily from the Boston Hill properties west of town. The ore averages better than 20% manganese. At Pinos Altos, rich gold-bearing quartz is being mined in the Pacific No. 2 workings of the old Skilacorn vein of the El Paso Mining Co. The company mill, which has been idle for the past two months, is about to resume operations. The shipment of lead and zinc ore from the Indian Hill shaft of the Manhattan group continues, 18 to 20 tons being hauled daily to the railroad at Silver City. The work of sinking the shaft at the end of the Manhattan adit has been resumed. The adit is in 900 ft. It is said that the shaft will be sunk 500 ft. It is reported that the Greybird claim of the Harvey property has been sold to parties from Mexico, and that they are also considering the purchase of the Mammoth mill. The U. S. Copper people suspended developments in May, but are expected to resume work August 1. Their two new double-compartment shafts are down 140 ft. and 50 ft. respectively. All machinery is in place on concrete foundations, and the new buildings are complete. The

Mountain Key mine may be re-opened this fall by a Silver City company recently organized. The Key shaft is down 900 ft. on an incline and full of water. Work at the Silver Cell property was suspended when diplomatic relations were severed between United States and Germany, as two prominent Germans controlled the company. The property has been kept unwatered, however. At the Calumet & New Mexico camp, development continues steadily, the ore taken out being sorted and the high-grade shipped. The average is better than 23% zinc and 25% lead. A good tonnage of low-grade ore has already been blocked out and the company contemplates the erection of a plant this fall.

W. H. Janney, president and general manager of the Re-

BLOCK OF SOLID ZINC SULPHIDE

public Mining Co., who for years was with the Chino Copper Co., at Hurley, since July 1 has devoted his entire attention to the management of the Republic property, where development is meeting with the expectation of its owners. Money has been judiciously spent and a great amount of ore is in sight. The ore carries lead, zinc, silver, and copper. The company will begin the construction of a 200-ton concentrating plant in the fall. The Hanover Copper Co. is continuously developing and shipping ore. The United States Copper Co. has cut a body of high-grade ore on its Philadelphia holdings and is making arrangements to ship. The ore assays 18% copper, besides carrying gold, silver, and iron. The Empire Zinc Co. never misses a day, the mill being kept at its full capacity. There are reports that the Chino Del Norte Co. has developed some good ore.

At Fierro the Hanover Bessemer Steel Co.'s new mill is a success and is operating full time. The Colorado Fuel & Iron Co., that was to have ceased operations June 1, will continue

until January 1, when the Hanover Bessemer Steel Co. will take over the mining of all properties under lease to the C. F. & I. Co. The McGee group of claims, 2½ miles north of Fierro, has been taken over by the Victoria Tungsten & Silver Mining Co. of Arizona, composed of Minnesota mining men. Development is to begin this summer. California men have been looking over manganese properties in this district the past month with a view to leasing.

At Santa Rita 10,000 to 11,000 tons daily is the regular output of ore made by the Chino Copper Co. Eight and nine trains per day of from 26 to 27 fifty-ton cars carry the ore to the company's plant at Hurley. Over 20,000 tons of ore and rock are handled every 24 hours. The high-grade ore is shipped to the smelter at El Paso. Recently one of the steam-shovels cut into a body of copper-glance, the extent of which has not been made public. The second big crusher installed the past year is in operation. A fine new club-house for the use of employees at Santa Rita is being erected by the company. Put-

the ore causing the company to curtail operations at the present. The Burro Grande Co. also is waiting for an opportunity to dispose of ore. The Giant Copper Co., a new organization having acquired over 1000 acres adjoining the Phelps-Dodge holdings, has a crew of men at work on the old National diggings. Another new company, the Federal Copper Co., has acquired holdings in the Burro Mountain district, and organization is being effected.

### CRIPPLE CREEK, COLORADO

A NEW PLANT FOR THE CATHERINE COMPANY.—A NEW WATER-COURSE CUT IN THE ROOSEVELT DRAINAGE TUNNEL.—VINDICATOR DECLARES A DIVIDEND.—OLD MINES RESUMING OPERATIONS.

Plans for mine-buildings and plants, to replace that destroyed by the recent fire, are being prepared for the Catherine Gold

TYPICAL SCENERY AT FIERRO, NEW MEXICO

ting all employees on the 8-hour basis and raising the wages of all employees 25c. per day on July 1, was voluntary on the part of the company. Over 1500 men are now employed. The Federal registration last month gave over 700 men for selective draft. At Hurley the mill of the Chino Copper Co. is being crowded to the limit of its capacity. Structural work for two additional units is completed and a big crew is installing machinery. Two miles south of the mill at the tailing-dam a new plant for the re-treatment of the tailing has been erected and operation is to begin this fall. The dams at this point are over a mile wide. Experiments with new types of tables, flotation-oils, and processes are made daily. The management is looking forward to the time when the still lower-grade ore on the dumps can be treated at a profit. The 8-hour day and the 25c. per day raise is effective here also. A new club-house for the employees is also being erected at Hurley by the company. The number of registrations for war duty at Hurley was 780, the greatest in the county. Frank R. Wicks succeeds W. H. Janney in the management here.

In the Burro Mountain district the Black Hawk property, reopened several months ago, is confirming the judgment of its owners. The Phelps-Dodge Co., at Tyrone, has created much outside interest in its development plans, not only in the mines, but in the successful operation of the new concentrator, and the recovery made by innovations. The Austin-Amazon Co. is working a small force at present, its inability to ship

Mining Co., of which Charles Walden, of Victor, is general manager. A new double-drum electric hoist, with a capacity for 2000 ft., and a 12-drill electrically driven compressor will be installed. The Catherine company holds a five-year lease and option on the Last Dollar Gold Mining Co.'s Last Dollar and Combination claims, on Bull hill.

The Roosevelt tunnel of the Cripple Creek Deep Drainage & Tunnel Co., has cut a new water-course in the Old Ironsides claim, of the United Gold Mines Co., on the west slope of Battle mountain. The flow is estimated to have reached 1000 gal. per minute when first tapped, and is now flowing steadily at 500 or 600 gal. per minute. The miners, who for many months have been working in heavy oil-skin coats and rubber boots, now work without the coats, the tapping of the water-course having an immediate effect on the drainage of the ground above. The tunnel-flow has raised again to about 6000 gal. per minute, of which about 3000 gal. is coming into the tunnel from east of the Elkton shaft, on Raven hill, and the remainder between the Elkton and Gold Dollar mine on Beacon hill, to the west.

The quarterly dividend of the Vindicator Consolidated Gold Mining Co., at the rate of 3c. per share, amounting to \$45,000, will be paid July 25. This will bring the dividend total for 1917 to \$135,000, and the grand total to \$3,667,500. The gross production from the Vindicator properties last year was reported at \$2,295,730 and \$1,644,120 net.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—Cache creek operators are having a successful season. A rich strike of quartz is reported on Thunder creek in this district. Reports from the Ruby district say that returns are encouraging. Flat and Tamarack are expected to yield big returns this season. Poorman creek has been the scene of another small excitement. Stephen Capps, of the United States Geological Survey, will work in the Broad Pass region until August. He will then go to Iron creek to investigate copper deposits and then across the divide to Willow creek.

The annual meeting of the officers of the Gold Cord and Mabel Mining companies will be held at Anchorage on July 10. A rich strike has been reported in the Mabel mine. A full crew is operating at the Martin property.

Plans for a power-plant for the Willow Creek district will not be carried out this year and Colorado people are looking into the matter with a view of putting in power of some kind next year. Louis Levensaler, a mining engineer, who for years was with the Alaska Syndicate, is at Unga island making an examination of the Apollo mine. Don S. Rae of the Rae-Wallace Mining Co. and Mr. Boomer, of Wallace, Idaho, are in town and developments of an important nature will be commenced on this property in the Willow Creek district, among other things the driving of a cross-cut adit and the installation of machinery.

Willow Creek, July 10.

## ARIZONA

### COCHISE COUNTY

Richard La Rue has discovered that the ore in his mine on White Tail creek contains molybdenite as well as lead and zinc. He had a carload of ore at the railroad station for shipment to the smelter when his attention was called to the presence of the molybdenite, a mineral with which he was unacquainted. He lost no time in reaching the railroad and stopping the shipment, until he could pick over the ore for the purpose of sorting out the molybdenite.

(Special Correspondence.)—Considerable excitement has been caused at Benson by the report of several Californian oilmen of the possibility of oil existing in the San Pedro valley. A company has been formed, the stock being issued publicly. It is only a matter of obtaining leases of sufficient area before test-drilling will commence.—The American Oil Fields Corporation has been formed with a capital of \$5,000,000. Two areas have been reported as favorable for oil, one in the China valley, the other in the San Pedro valley.

Benson, July 26.

### GILA COUNTY

(Special Correspondence.)—Development work is progressing favorably on the Magma Chief, according to reports of the superintendent, C. A. Kumke.

Globe, July 26.

### MOHAVE COUNTY

(Special Correspondence.)—Within two weeks of the discovery of ore in the Telluride mine, the drift at the 400-ft. level of the neighboring property, the Sunnyside, opened up stringers of quartz of good grade. The drift was advanced 340 ft. north-west from the shaft, and to avoid timbering, the work was done in the solid ground adjoining the vein. When directly under the old 100-ft. shaft a cross-cut was run 18 ft.

across the vein with no hanging wall in sight, and containing stringers of quartz and calcite, and silicified andesite.

A drift was run along the foot-wall opening up a 2-ft. vein of quartz assaying \$10 per ton in gold and increasing in width and value. The drift will be continued for 100 ft. on the theory that this is the east end of an orebody.

For the first six months of operation of the United Eastern, the general superintendent, J. A. Burgess, reports a total of 37,565 tons of ore milled, having a gross value of \$793,497, averaging \$21.12 per ton. A net profit of \$491,130 was realized from operations. The initial dividend of 5c. per share will require about \$70,000, but after this and all current indebtedness incident to the construction of the mill has been paid, the company will have a considerable surplus in the treasury.

With an increase in milling capacity to 300 tons per day, the second half of the United Eastern's operation should excell the record made from January to July.

Oatman, July 26.

(Special Correspondence.)—The reported rich strike on the Telluride vein at Oatman is proving more important than at first supposed. The ore is 4 ft. wide. At the Smuggler group ore worth \$300 per ton is mined from an 18-in. vein. This mine has shipped considerable high-grade ore in the past. The Golconda mine, of the Union Basin Mining Co., has adopted the Oatman-Chloride scale of wages, granting an increase of 25 to 30 cents per day in wages, and has resumed operation.—R. S. Billings, of Los Angeles, reports the discovery of large low-grade deposits of molybdenum ore. The molybdenum belt is claimed to be three miles wide and 35 miles long, covering several groups of claims, chief of which are the Copper Taylor, Acme Molybdenite, and the Great Republic.—Financial arrangements have been made in Los Angeles for the re-opening of the old Leland property. It is expected that the new 300-ton mill of the Washington-Arizona at Mineral Park will commence operations in a few days.—J. J. Ford, representing Pittsburg financiers, has examined the property of the Grand Canyon Gold Co. Plans have been completed for the working of these placer deposits on the Colorado river.

Oatman, July 25.

### PINAL COUNTY

(Special Correspondence.)—It is reported that the Silver King shaft is to be pumped out and the mine re-opened; financial arrangements are now being completed. This is a famous old silver property, but the records show that there is copper on the 800-ft. level and it is expected it will become a copper producer.

Florence, July 25.

### SANTA CRUZ COUNTY

According to *The Oasis* of Nogales the old Mowry mine is to be re-opened and equipped with a 50-ton concentrating mill. J. C. Smith and Sidney Bennet, of western Pennsylvania, who are largely interested in the property, recently visited the mine and decided to start the work of rehabilitation.

### YAVAPAI COUNTY

Arizona papers state that all of the important mines in the Jerome belt that were affected by the recent labor disturbances, have resumed operations. At the United Verde a 'weed-ing-out' process has been instituted and the undesirables are being given their time. As they will be unable to secure employment in the district they are leaving and no further trouble is anticipated.

## CALIFORNIA

## CALAVERAS COUNTY

The Calaveras Copper Co. at Copperopolis will sink a new vertical 3-compartment shaft to open the North Keystone claim. It is proposed to mill the old dumps, which are fairly rich in copper. The rock will be loaded into cars with a steam-shovel.

## DEL NORTE COUNTY

(Special Correspondence.)—At the Diamond Creek cinnabar property the machinery is being set up by the owners, Ehrman, Cole & Taggart, and they expect to be ready to begin producing quicksilver within two weeks.

Waldo, Oregon, July 24.

## EL DORADO COUNTY

The hoisting and milling machinery and buildings of the Larkin mine, near Diamond Springs, were destroyed by fire July 21. The Griffith mine property narrowly escaped similar destruction. The loss was caused by a brush fire that swept over that district.

## MADERA COUNTY

It is proposed to explore the extent and character of the iron-ore deposits in the Minarets district by means of bore-holes, says *The Inyo Register*. The work is understood to be in the interest of the Noble Steel Co., and will be in charge of Henry Beck, who is now at Bishop waiting for the arrival of the drilling outfit.

## MARIPOSA COUNTY

(Special Correspondence.)—E. C. Gamble and W. S. Stewart, of Oakland, have sampled the Sweetwater mine east of Mariposa and made a mill-test of the ore, and contemplate working the mine under lease and option. Thomas Doyle, of Fresno, is doing development on the Filiciana mine. The Early mine has been unwatered and re-timbered and has resumed operations. A 50-hp. gas-engine has been placed in the mill and 10 stamps are dropping. W. H. Washburn is in charge of the mill. On the 200-ft. level a shoot of rich ore has been found at the intersection of two veins. Geo. H. Hook is superintendent.

Jerseydale, July 16.

## NAPA COUNTY

Napa county produces other mineral than quicksilver. Clark & McLean, of New York, have leased a number of cinnabar properties near Mt. St. Helena, and will develop them. Within the past month there has been shipped from Calistoga 500 tons of chrome, four cars of fine kaolin, 40 flasks of quicksilver, and three cars of gold and silver ore from the old long-neglected Silverado mines. Regular shipments are to be made from these mines.

## SANTA CLARA COUNTY

(Special Correspondence.)—Mrs. Stock has closed a contract for a lease of her magnesite claims on Red mountain to Bodfish and McGuire, of San Francisco, who will develop the property and ship the magnesite by auto-trucks, under contract to Livermore. When the deposits have been developed, a rotary kiln will be placed on the mines. There is said to be 5000 tons of ore in sight.

Livermore, July 28.

## SHASTA COUNTY

(Special Correspondence.)—F. S. Hink, of Oakland, and R. V. Montgomery, of San Francisco, have taken a lease and option on the Central mine in Old Diggings. The mine will be sampled with a view to purchasing. A. A. Anthony of Old Diggings owns the mine.

The Arps Copper Co., at Copper City, has shipped its second carload of ore to the smelter at Kennett. The company contemplates providing reduction works of its own.

At the Star mine, one of the Bully Hill Copper Co.'s proper-

ties, 55 men are employed. The mine has been unwatered to the 900-ft. level and development will be continued. The mine has been idle since the Bully Hill company abandoned operations 10 years ago, on account of the smelter-fume trouble. L. C. Monahan is superintendent.

Redding, July 24.

## SIERRA COUNTY

A small but rich vein of quartz has been found in the bed-rock of the Mohawk drift mine on Dock creek. It has already produced a quantity of very rich gold rock.

## TUOLUMNE COUNTY

The main shaft of the Clio mine, half a mile above Jacksonville, on the Tuolumne river, is to be unwatered for the purpose of cross-cutting into the foot-wall to explore the slate vein on the 600-ft. level.

## COLORADO

## BOULDER COUNTY

(Special Correspondence.)—The sale of the Bradenbury group of gold properties on Left Hand has been made, and C. D. Colburn and associates, of Denver, will assume control. The annual meeting of the Degge-Clark Milling Co. was held this week. The stockholders approved the sale of the milling plant. The property is in good condition and making a large production. It is being worked by lessees.

The U. S. Gold Mining Corporation is developing its holdings. A large amount of oxidized mill ore is exposed. The noted Livingston mine, one of the properties, has a large vein. The White Raven property, one of the largest silver-lead mines in the county, is making heavy shipments. It is owned by L. A. Ewing and partners. Jamestown, situated in the centre of the Central mining district, after many years, has revived.

Eldora, July 24.

## IDAHO

## SHOSHONE COUNTY

(Special Correspondence.)—Free rent of company houses, free light and water, and no interest on building-loans will be the 'bonus' which employees of the Bunker Hill & Sullivan company, at Kellogg, who enlist in the army or navy will receive. A large number of men have already gone into the army or navy, and in the draft scores of men employed by the company were called.

Spokane, July 23.

## MICHIGAN

## HOUGHTON COUNTY

Production of copper during June by the Calumet & Hecla and subsidiary companies was as follows:

Mines	Lb.	For the year, lb.
Ahmeek .....	2,530,848	14,880,459
Allouez .....	755,399	4,806,688
C. & H. ....	6,346,446	40,194,517
Centennial .....	143,907	923,859
Isle Royale .....	1,240,050	7,383,234
La Salle .....	157,546	1,010,823
Osceola .....	1,327,773	8,809,579
Superior .....	193,050	1,211,375
Tamarack .....	241,703	3,004,841
White Pine .....	410,803	2,134,394
Total .....	13,347,525	84,359,769

The Calumet & Hecla Mining Co. and subsidiaries produced a total of 84,359,769 lb. of copper in the first half of 1917, an increase of 4,478,213 lb., or 5% over the same period in 1916. The subsidiaries making relatively the best showing were Ahmeek and Isle Royale, with increases of 22% and 18%, respectively. Osceola dropped off 10%. The copper product was

sold at probably the highest prices ever quoted for any six-months' period in the history of the industry, but unfortunately such of it as was exported was sold f.o.b., London, the shipper being obliged to stand the heavy transportation charge, war-risk, and marine insurance. This probably jumped costs 3 to 4 cents per lb., so that combined with rising costs in other directions, the final net was probably no larger than for the last half of 1916.

## MONTANA

### LEWIS AND CLARK COUNTY

(Special Correspondence.)—Ore shipments from the Scratch Gravel Gold Co. property in the Scratch Gravel hills average nearly \$4000 per car at the East Helena smelter. The last car netted \$3736. The ore was mined from the 300-ft. level and consists of gold-bearing quartz. The shaft is an incline, 500 ft. deep.

At the Julia mine, in Scratch Gravel hills, the shaft is down 250 ft. on the incline. Ore is coming from the 170-ft. level. It contains silver, lead, and gold. In the bottom of the shaft there is 2 ft. of low-grade ore with bunches that run well in gold and silver.

The Cruse Development Co. has paid well and is the best and most extensively developed in the Scratch Gravel hills. The incline-shaft is down 600 ft. The ore carries gold almost exclusively.

In the Grass Valley district the Helena mine is developed to a vertical depth of 300 ft. The ore is silver-lead and shipments are going out. The average smelter returns are at the rate of about \$35 per ton.

The Rock Rose shaft, in the same district, is down 300 ft. vertically, in hornstone for the last 100 ft. The ground is traversed by many veins and porphyry dikes. Good ore was found at the 200-ft. level, but no ore is to be stoped or shipped before the 300-ft. level has been reached. More water is coming into the shaft, which here is regarded as a good indication. Driving on the 300-ft. level and stoping on the 200-ft. level is to begin before August 1. No ore has been mined from the property below the 100-ft. level. The ore carries silver, lead, and gold and is sent 8 miles to the East Helena smelter.

Helena, July 16.

The re-modeled Drum Lummon 25-stamp mill at Marysville is crushing 80 tons per day of stope-fillings from the Drum Lummon mine. The material is low grade, but pays well, according to the management. The property is operated by the owners, the St. Louis Mining & Milling Co. Forty men are employed. All machinery is driven by electric power.

Prospecting for new orebodies is under way at the Bald Butte mine and some good ore is reported, but as to its extent nothing has been given out. The Bald Butte mine has paid in dividends \$1,500,000. Prospecting is being done in new ground.

The Helena mine, belonging to the Helena Mining Bureau (incorporated), is taking lead-silver ore from the 300-ft. level. The streak is from 1 to 3 ft. wide.

James Coffey has made a small shipment from his mine in Grass Valley to the East Helena smelter. It assayed as high as \$500 in silver and lead.

The Rock Rose Co.'s vertical shaft is down 315 ft. and cross-cutting is going on at the 300-ft. level, and driving on ore at the 200-ft. level. The shaft is in hornstone from the 200-ft. level down.

The Producer mine in Dry gulch is being developed by adit and raise. A 2-stamp mill is in operation. The ore is low grade, but bunches occur that are rich in gold.

In the Katie property, in Scratch Gravel hills, an ore that is a heavy sulphide of copper and lead, and that averages about \$100 per ton at the smelter, has been discovered.

There is more developing going on about here than ever before in the history of Helena. Five companies are operating in Grass Valley and three others are at work at Marysville. In the Scratch Gravel hills the Thomas Cruse Development

Co., the Scratch Gravel Gold Mining Co., the Julia syndicate, the Blue Bird lessees, and the Katie are at work, besides which many small mines are being prospected.

The Snow Drift-Penobscot, at Marysville, is idle and no work of consequence has been attempted there in many years. The Whitlatch property is being worked on a small scale by lessees. They have good milling gold ore near the bottom of the 500-ft. shaft. Water, which was expected to interfere with work in the shaft, did not materialize as it percolates through the limestone to the long adit driven north to intersect other veins.

The Big Indian mine has been abandoned and the electric pole-line to the mine from East Helena has been removed as well as the 60-stamp mill and other machinery. The Big Indian ore became base with depth and was no longer profitable.

There appears to be a good chance for the Whitlatch mine to be worked again. But it may depend upon action by the owners of the Spring Hill property to the north. It was expected

MAP OF REGION ABOUT HELENA

at Helena that the Spring Hill would be purchased and worked on a large scale this summer, but nothing has been done as yet. Poor dumpage and abundant water are the principal drawbacks. The orebody is said to be extensive and is reported to average \$7 gold per ton. The ore is a quartz-diorite, in which pyrrhotite prevails. The Whitlatch and Spring Hill are expected to be worked simultaneously. But when this will be is problematical.

Helena, July 24.

### SILVERBOW COUNTY

The mining companies at Butte have announced a new sliding-scale of wages for underground miners, which grants an increase of 50c. per day, based on the present price of copper, making the daily wage \$5.25, says the *Boston News Bureau*. The minimum wage remains at \$3.50 per day with copper at 15c. or less, advancing to \$6 per day with copper at 31 to 33c., with 25c. additional for each 2-cent advance in metal price thereafter.

All unclassified men are to get a raise of 25c. per day, and shaft-men an additional 50c. above the rate for ordinary miners. A weekly pay-day is established and the rustling-card system modified.

It is believed that the new scale will prove satisfactory to a large majority of the striking miners as they are granted practically all they asked for with the exception of absolute abolition of rustling-cards.

I. W. W. strikers, however, have not given up the fight and are threatening to begin picketing mines Wednesday. They have served warning on boarding-house keepers not to put up lunches for miners who work. They are promising miners \$6 per day for four hours' work eventually if they will not

return to work now. Outside of the miners, the metal trades at Butte are voting against acceptance of new rates offered to them by mining companies.

## NEVADA

### CLARK COUNTY

(Special Correspondence.)—The Duplex property is now expected to produce a large tonnage monthly. Last week E. F. Griffith and Andy Tomey shipped two carloads to the Selby Smelting & Lead Co., from a lease on this property. George Colten also shipped 37 tons of high-grade copper, gold, and silver ore from the property to Selby.

James Cashman, of Searchlight, and William Erwin, and William Crozier of Eldorado Canyon, shipped to Selby a carload of ore from a lease on the Rand Mining Co.'s property. The car was shipped July 3. The ore assayed over \$300 per ton.

Charles Spencer, leasing on the Tex Evins property, shipped a carload of good gold and silver ore to the Garfield smelter on July 6.—Booth & Castle, lessees on the Searchlight Parallel Gold Mining Co.'s property, again shipped a brick to Selby, the result of a run at the mill on the Searchlight Spokane property.

The Edward Cebrian Cyanide Co., that has been treating the tailing at the Quartette mine, was closed down for the past few months owing to the high cost of cyanide, but expects to start up again in a few days. The handling of the water has been successfully arranged. The States Mutual Consolidated Mining Co. is making preparations for extensive development at the copper camp. Frank E. Sharp, who is interested in the Big Casino and the Chief of the Hills Mining companies, has taken over the Bonanza-Spokane. A new shaft is being sunk 300 ft. north-west of the old shaft. The new shaft is in ore from the surface. Two shifts are working and a hoist will be installed at once. The property is equipped with a 10-stamp mill and electrical equipment. The Chief of the Hills Mining Co. is overhauling its hoisting machinery, and the mill is in readiness.

Searchlight, July 25.

### ELKO COUNTY

It is reported that E. R. Holden is to build a 300-ton smelter at Tuscarora to treat the ore on the dumps of the old mines of that district, according to the *Elko Independent*. There is a large amount of ore on the dumps and it is thought that under existing conditions the proposed enterprise will be profitable.

### EUREKA COUNTY

(Special Correspondence.)—W. A. Barnes has taken an option on the Holly mine situated on Adams hill, two miles north of Ruby hill, of which it is a prolongation. Work is progressing for the purpose of exploration and development.

Eureka, July 24.

(Special Correspondence.)—The mill clean-up of the West End for the first half of July consisted of 29 bars valued at \$49,000. The ore came from the West End and Ohio shafts, as the Halifax-Tonopah is cross-cutting on the 17th level and will not resume stoping on the 12th level until the old square-set stope has been filled.

At the West End shaft driving east is in progress in 717 D. No. 3. As the drift is in a fair grade of ore considerable territory will probably be explored. The Ohio continues to supply the mill with ore, and cross-cutting is in progress southward and raising to the vein.

The recent strike in the Monarch-Pittsburg, of a 3-ft. vein of good ore, will soon place them on the shipping list, as they are driving on the vein with 80 ft. of backs.

During June the Tonopah Mining Co. produced 8177 tons of ore of an average value of \$17.66, making the total value of \$136,145, of which \$54,750 represented net profit. The development work of the Tonopah Mining Co. the past week has been

in the Sandgrass and Silver Top shafts. The ore is also coming from the Mizpah, the value of the ore for the previous week being \$35,000.

At the Tonopah Extension development consisted of 36 ft. in the Murray shaft and 79 ft. in the Victor, on the 1440-ft. level and the 1540. At the latter the completion of the 1680-ft. station, which is 140 ft. below the previous workings, will be finished in three weeks and cross-cutting south to the Murray vein will commence. The total production for the week amounted to 2400 tons.

During June the Tonopah Belmont company produced 11,416 tons of ore, making a net profit of \$106,989, which is the largest June net earnings in the camp, made possible by the advanced price of silver, for the tonnage was nearly 1000 tons less than in May, while the net profits increased \$8000.

Raise 90, on the 1100-ft. level of the Belmont, continues to follow the Rescue vein, which is 3 ft. wide.

The Jim Butler Tonopah Mining Co. sent 2925 tons of ore to Millers for treatment in June resulting in a net profit of \$50,136.

Tonopah, July 24.

## NEW MEXICO

### SOCORRO COUNTY

(Special Correspondence.)—The Socorro Mining & Milling Co.'s clean-up for the last half of June amounted to 17,000 oz., making 35,000 oz. for the month. The Mogollon Mines Co. marketed during the same period about 30,000 oz., or a total of about 65,000 oz. of new gold and silver for the month. High-grade concentrate also was made and shipped direct to the smelter. Shipments are being made by this company from the Maud S. mine as well as occasional shipments from other properties being developed by it.

Mogollon, July 18.

(Special Correspondence.)—The Socorro Mining & Milling Co. cleaned up 16,000 oz. of bullion for the first half of July. The milling plant is being run to capacity.

The Oaks company has completed the head-frame for the new Central shaft. A hoist has been installed and the shaft-house is being built. This company is doing considerable development in the Maud S. mine and is maintaining daily shipments to the mill from development. The main part of the mine will be opened through the Central shaft on Deep Down ground.

The tailing-flume being built by the Mogollon Mines Co. is completed nearly to the Harry tunnel. This has been carried on steel cables through the box-canyons and is giving good satisfaction. It is the plan to run this flume to the main tailing-dam on Mineral creek, three miles below camp.

Mogollon, July 23.

## OREGON

### JOSEPHINE COUNTY

(Special Correspondence.)—The Turk copper mine, which is owned by the Grants Pass Hardware Co., is under option and is being prospected by M. A. Delano.

Takilma, July 25.

(Special Correspondence.)—A carload of gravel has been shipped from the Osgood placer mine, in Allen gulch, on which a test is to be made. The Preston Peak copper mine is being prospected with a diamond-drill. The mine is owned by a Chicago stock company.

Waldo, July 23.

(Special Correspondence.)—W. S. Baker, of Buffalo, New York, one of the owners of the Greenback mine and other properties in this district, which are being developed by the same interests, is here and will remain to take personal charge. It is reported that G. W. Finch is developing a copper property on Rogue river, in Curry county, at Agness.

Grants Pass, July 24.

## TEXAS

## BURNET COUNTY

(Special Correspondence.)—The holdings of the Texas Graphite Co., situated near Burnet, 50 miles north-west of here, were sold recently at receiver's sale to Victor Brooks, of Austin, as trustee for Albert Burrage, of New York, Ralph Arnold, of Los Angeles, California, and others. The purchase price was \$50,000. The purchasers were the same men who composed the company. The property is said to represent an investment of more than \$200,000. It is the purpose of the purchasers as soon as the sale is confirmed by the Federal District Court here to resume the development and operation of the property.

Austin, July 22.

## PRESIDIO COUNTY

(Special Correspondence.)—A large deposit of cinnabar has been discovered near Candelaria, a short distance from the Rio Grande, 75 miles south-west of Alpine. The original claim was taken by J. M. Ingle of Candelaria. Other promising prospects have been taken up and extensive development will follow, including the building of one or more quicksilver furnaces. This new field is situated 90 miles north-west of Terlingua where cinnabar mines have been operated for years. The Terlingua properties are 90 miles from Alpine, which is the nearest railroad shipping point. The discovery near Candelaria is 30 miles from the station of Valentine, on the Southern Pacific.

Alpine, July 23.

## REEVES COUNTY

(Special Correspondence.)—Alfred Tinally, of Detroit, Michigan, and his associates have purchased large deposits of sulphur near here and are preparing to work them. Their plans include a plant for refining the crude sulphur and the construction of a railroad from Pecos 40 miles to the mines. Large quantities of crude sulphur are being mined west of here and the product is selling for \$25 per ton loaded on cars at the railroad.

Toyah, July 25.

## UTAH

## SALT LAKE COUNTY

W. J. Moore, H. A. Steinmetz, and A. S. Christian, Federal inspectors from Washington, on July 23 began a systematic investigation of the books of the Utah Copper Co., says the *Salt Lake Tribune*, presumably to arrive at the cost of producing copper at the property. It is expected that the investigation will be extended to other copper companies and to other metals than copper.

## BRITISH COLUMBIA

(Special Correspondence.)—Five feet of ore containing 10% copper has been opened in the No. 1 vein on the 1000-ft. level of the Rocher de Boule mine, near New Hazelton, B. C. This is the orebody from which was shipped \$1,500,000 worth of ore up to January 1, 1917, from the upper workings. The shoot is being sought at the 1200-ft. level by a cross-cut tunnel now in more than 3000 ft. This tunnel will be continued 4000 ft. where it will open on the opposite side of the mountain.

New Hazelton, July 22.

## CAPE BRETON ISLAND

An explosion of gas in the coal mine of the Dominion Coal Co. at New Waterford on July 25, resulted in the death of 62 miners. The work of rescue of men who were not killed was hampered by deadly gas, and by the caving of the mine workings. Again, as recently at Butte, a mere boy, Jack McKenzie, who went into the mine with the rescue crew and aided in removing a number of men finally lost his own life by asphyxiation.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

ROBERT STICHT is at Pasadena.

BEN. B. LAWRENCE is due here from New York.

W. A. BARNES has returned to Eureka, Nevada.

FOREST RUTHERFORD has gone to Pueblo, Colorado.

A. H. ROGERS has returned to Boston from California.

H. R. NORSWORTHY is examining placer mines near Boise, Idaho.

FRED. B. GOETTER, formerly at San Dimas, Mexico, is now at Los Angeles.

HENRY E. WOOD, of Denver, is here, on his return from Shasta county.

EARL B. CRANE is manager of the Black Butte quicksilver mine, in Oregon.

J. S. DILLER, of the U. S. Geological Survey, is in southern Oregon inspecting chrome deposits.

F. A. BEAUCHAMP, of the firm of Beauchamp, Hamilton & Woodworth, has returned from Arizona.

PETER H. NISSEN, of the Nissen stamp, is now Lieutenant-Colonel, besides having received the D. S. O.

WILLIAM W. MEIN and WALTER KARRI-DAVIES have gone to the Le Pas copper-mining district in Manitoba.

CHARLES O'BRIEN is on his way to Salvador mines, to serve as metallurgist with the Butters Salvador Mines.

R. A. HARDY has succeeded E. L. S. WRAMPMEIER as manager for the Montana Mines Company at Ruby, Arizona.

CARL R. DAVIS, general manager for the Brakpan Mines, Ltd., will visit the United States in the late summer and fall.

E. GYBON SPILSBURY sailed from New York on July 26 for Central America and expects to be absent until the end of August.

CHARLES F. WILLIAMS, recently mining engineer at Cananea, Mexico, is with the Tonopah Belmont Development Co. at Tonopah.

W. L. HONNOLD, who has been serving as director, at New York, for the Commission of Relief in Belgium, is expected here next week.

HERBERT W. GEPP has resigned as manager for the Amalgamated Zinc Co. to become manager for the Electrolytic Zinc Co. in Australia.

E. L. S. WRAMPMEIER has resigned the management of the Montana Mines Co. at Ruby, Arizona, and now has headquarters at Tucson.

E. S. KING passed through San Francisco on his way to New Zealand, having been appointed manager of the Waihi Grand Junction mine.

HOWLAND BANCROFT has gone to New York, where he will be at the Engineers Club until about the middle of August, after which he will return to Denver.

E. L. LABISON has resigned from the Anaconda Copper Mining Co. to accept a position with the Garfield Chemical & Manufacturing Corporation in Utah.

JOHN G. KIRCHEN will make his headquarters at Reno. ALIENE CASE is superintendent of the Tonopah Extension mines, under direction of Mr. Kirchen.

KIYOSHI SHIGA, physicist to the Metallurgical Research Institute, of Tokyo, has been visiting metallurgical plants in this country and is now returning to Japan.

GEORGE A. TWEEDY, formerly general manager for the Minas del Tajo, Rosario, Mexico, has gone to Honduras, Central America, to examine the old long abandoned mines at Opeteca, near El Espino, in the Department of Comayagua.

# THE METAL MARKET

## METAL PRICES

San Francisco, July 31

Aluminum-dust (100-lb. lots), per lb.	\$1.00
Aluminum-dust (ton lots), per lb.	\$0.95
Antimony, cents per pound	15.50—18.00
Electrolytic copper, cents per pound	31.00
Pig lead, cents per pound	12.25—12.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound	10.50
Tin, cents per pound	60
Zinc-dust, cents per pound	20

## ORE PRICES

San Francisco, July 31

Antimony, 50% metal, per unit	\$1.20
Chromite, 40% and over, f.o.b. cars California, cents per unit	50—55
Magnetite, crude, per ton	\$8.00—10.00
Tungsten, 60% WO <sub>3</sub> , per unit	26.00
Molybdenite, per unit for MoS <sub>2</sub> contained	\$40.00—45.00
Manganese, 45% (under 35% metal not desired), cents, unit	33—37

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese	Per unit \$1.00
46 to 49% metallic manganese	0.98
43 to 46% metallic manganese	0.95
40 to 43% metallic manganese	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option, settlements based on analysis of sample dried at 212° F. the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

During 1916 there was shipped from Panama mines manganese ore to the value of \$328,684. Further expansion of this industry is reported as probable. Brazilian manganese mines, which are reported to be extensive, are being worked and an increasingly larger tonnage shipped. The industry there is hampered by the difficulties of cheap transportation.

## EASTERN METAL MARKET

(By wire from New York)

July 31.—Copper is firmer but nominal at 28 to 28.50c. Lead is dull and higher, closing at 10.75c. Zinc is quiet and steady at 8.75c. throughout the past week. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
July 25	78.37
" 26	78.37
" 27	78.12
" 28	78.12
" 29 Sunday	78.12
" 30	78.12
" 31	78.62

## Monthly Averages

Date	1915	1916	1917
Jan.	48.85	56.76	75.14
Feb.	48.45	56.74	77.54

May	49.87	74.27	74.61
June	49.03	64.04	76.44

A compilation by National City Bank shows that silver production of the United States is now double that of Mexico and three times that of Canada, which holds third rank among silver producing countries, says the "Boston News Bureau." Of 172,383,000 oz. produced in the world in 1916 the United States produced 72,833,000, or 42%, while 20 years ago, in 1896, we produced but 37% of world production, in that year 157,061,000 oz. In that 20-year period, 1896 to 1916, production of the United States has increased about 14,000,000 oz., while that of other parts of the world increased only about 1,000,000.

The chief producers are the United States, Mexico, Canada, Peru, Japan, Spain, Australia, and Chile, in order named, the United States having produced, in 1915, 74,961,000 oz., Mexico 39,570,000, Canada, 28,401,000, Peru 9,420,000, Japan 5,080,000, Spain 4,565,000, Australia 3,327,000; world total 179,574,000. In 1916, for which returns are not yet available for many smaller countries, production of the United States was 72,834,000 oz., Mexico 35,000,000, Canada 25,500,000, and the world total 172,384,000 ounces.

May	18.71	29.02	31.89
June	19.75	27.47	32.57

Copper production from the principal mines and smelters of North and South America approximated 1,085,815,413 lb. during the first six months of 1917. But for the miners' strikes which started in June, output would have been considerably greater. The Butte district in June showed a substantial falling off due principally to Anaconda's drop from 28,000,000 to 20,000,000 lb. In Arizona losses were general, all the properties with the exception of Ray Consolidated being tied up by strike. The Alaskan properties of Kennecott Copper Corporation were also shut-down with the exception of the Beatson mine.

June's total copper yield was about 167,000,000 lb., comparing with 190,000,000 lb. in May. The July production will be far less than that of June, as some of the mines will not have turned out a single pound of copper during July.

The dividend of Greene-Canaan Copper Co. which was recently declared is the first dividend of the company since the sale to it of the assets of Greene Consolidated Copper Co. The Greene-Canaan Copper Co. now receives its dividend direct from this Mexican corporation instead of through the Greene Consolidated Copper Co. as formerly. Therefore holders of Greene Consolidated Copper Co. stock who have not yet converted their shares into Greene-Canaan Co. stock will do so before the stock becomes ex-dividend on August 15 if they wish to participate in this dividend. Eighty-cent silver will be of considerable aid to copper producing companies, which also recover silver as a by-product, in offsetting to some extent their rapidly rising copper costs.

## Eastern Metal Market

New York, July 25, 1917.

It is still a waiting and restricted market, almost paralyzed in some departments, held up by the indecision of the Government purchase and price-fixing policy. Quotations are largely nominal and sales are of small volume in almost every case.

Copper continues to decline and is lower.

Tin is quiet and dull but steady.

Lead has stiffened somewhat after a week of declining prices and little business.

Zinc is steadier after a period of weakness.

Antimony continues its decline, with demand small.

Aluminum has fallen on poor demand and more offerings.

Steel buyers and consumers continue to hold aloof, prompted by the fear of what will happen to prices if the Government pursues its one-price-to-all policy. Evidence is accumulating that the problem of determining a representative cost of any form of finished steel is turning out to be more difficult than was expected at the outset. It is hoped that this realization may lead to abandonment of the task. The shipbuilding programme, as now planned for the coming year, will require almost 1,000,000 tons of plates, or about 50% of what ship-plate mills can produce. In no other steel line will the Government proportion be so large—not as press reports have said: "the Government requiring the entire maximum output of the mills for some time to come."

### COPPER

The influences controlling the copper situation are practically the same as those mentioned last week—Government purchases, the amount, and the price. Nor is there any definite information obtainable that will ease a situation that has nearly paralyzed not only copper but other markets. The feature of the week has been an unlooked-for drop in the London market. Spot electrolytic is now quoted at £137 with futures at £133, a decline of £5 per ton from a price which has remained stationary for a long time. Some regard this as an attempt to bear the market on this side, while others are inclined to think it will result in a better understanding as to quotations between large and small producers and perhaps have a stabilizing influence. In the past week there has been little business reported, though some sales of moderate proportions were made for September-October delivery at 24.50 to 25.50c., New York. Sales, however, for most positions were not enough to establish a market and quotations which are mostly nominal have been established by offers and not by actual transactions. Yesterday the quotation for both Lake and electrolytic copper was 26c., New York, for early delivery, or July and August, with fourth quarter generally held nominal at 24c., New York. Exports of copper are estimated at 40,000 gross tons for June, bringing the total for the half year to nearly 266,000 tons or about twice the total to July 1, 1916, of 147,943 tons. Imports for the same period have been 114,000 tons this year, against 103,500 tons last year. The June output of refinery copper is estimated at 200,000,000 lb., with the total for the first half of this year at 1,055,000,000 lb., contrasting with a total for 1916 of 2,259,000,000 lb. One commentator says that in ordinary times the requirements of public-service companies are about two-thirds of the copper consumption of the country, but at present they are probably only one-sixth to one-third of the total amount now annually consumed.

### TIN

In the past week sales have been moderate in volume and importance and the market has been dull and quiet. Such sales as have been reported have been mostly early shipment from England or future shipment from the Straits Settle-

ments. The market feature has been a pronounced scarcity of spot-tin. This has been due to unwillingness in England to grant shipping permits, and to the slowness by American buyers to commit themselves. No other attitude can be expected with the question of price regulation still dominant and holding up the market. There has been some little desire to sell tin in some quarters, but on the whole cautiousness rules. The market has been almost a nominal one at 62.50c. the entire week since July 19, the quotation on July 20 having been 62.62½c., New York. The London market is dull and unchanged from last week at £237 10s. for spot Straits.

### LEAD

The conviction is firm in the trade that large quantities of lead will be wanted for war and other purposes, but until yesterday the market had not recovered from its scare of last week regarding the one-price-to-all policy as proclaimed by the President. Buyers were extremely cautious and adopted a 'play-safe' policy. Offerings were more or less liberal, coming from second-hands and from consumers, and the market declined until 10c. lead, New York and St. Louis, was the prevailing price at the end of the week. Large producers are having their labor troubles also. The latter part of last week lead was obtainable at 10c., New York, with some sales reported at 10c. for August-September shipment. Yesterday the market stiffened, due either to the withdrawal of the offerings referred to, or to their having been sold, and it was difficult to obtain lead under 11c., New York, which continues to be the quotation of the American Smelting & Refining Co. There were, however, small quantities sold here and there at 10.25c., New York and St. Louis, with also about 100 tons going at 10c. The quotation yesterday, therefore, is put at 10.25c., New York and St. Louis, though the broad market is from 10.50 to 11c., with an advance probable.

### ZINC

After falling to the lowest point in some time, the market for prime Western spelter has grown somewhat stronger. There is more inquiry than for some weeks, but the volume is not large. Consumers, at least some of them, are realizing that spelter is cheap or too close to the cost of production and hence are inclined to display more interest. Added to this is the strengthening expectation, almost amounting to an assurance in some quarters, that the Government is about to negotiate for its needs for the rest of this year. A settlement of this question would be a stabilizing influence of decided benefit and importance to the whole market. Today the market is higher if anything than yesterday and is generally quoted at 8.50c., St. Louis, or 8.75c., New York, for early or future delivery. Sales of small lots of 50 or 100 tons each are reported as having been made at 8.37½ to 8.62½c., St. Louis, or 8.62½ to 8.87½c., New York. There is more interest in future delivery than in prompt or nearby, but not so much inclination to sell far ahead. A report is current today that a sale of 225,000 tons of prime Western has been made to the Government at 8.75c. per lb., St. Louis, for delivery the rest of the year, but no confirmation is obtainable.

### ANTIMONY

Two lots of 25 tons each were sold in bond yesterday and Monday under the hammer on the Metal Exchange at 13.37½c. per lb., which is equal to about 14.50 to 14.75c. per lb., duty paid. The market, however, is very quiet with Chinese and Japanese grades at about 15c., New York, duty paid.

### ALUMINUM

There are more sellers than buyers and the market is lower at 53 to 55c., New York, for No. 1 virgin metal, 98 to 99% pure.

# INDUSTRIAL PROGRESS

*Information furnished by manufacturers*

## An Optical Pyrometer for Works Use

For the measurement of temperatures above, say, 1400°F., only two methods have been found practicable for works-service. One of these is based on the thermocouple, used either

THE LEEDS & NORTHRUP OPTICAL PYROMETER IN USE

with the millivoltmeter or with the more accurate and reliable potentiometer. The other method is based on the laws of radiation and includes both the radiation-pyrometer, which would be more properly named the 'total-radiation' pyrometer,

THE LEEDS & NORTHRUP OPTICAL PYROMETER

and the optical-pyrometer, which utilizes only that radiant energy visible to the human eye.

For many services the inexpensive and sturdy base-metal

couple may be used for accurate measurement up to 2000°F. with entire satisfaction; the more fragile and expensive platinum-couple may be used up to 2800°F., but the thermocouple, like thermometers in general, must assume the temperature of the hot object by convection, conduction, radiation, or all combined. This fact militates against its use for measuring temperatures of molten brass, iron, and other metals, or for measuring temperatures in gas-producers and other places where the thermocouple would be subjected to rough mechanical treatment or to contamination by vapors and gases, which would rapidly impair its accuracy. In many industries the

CASE CONTAINING BATTERY, RHEOSTAT, AND MILLIAMMETER FOR USE WITH OPTICAL PYROMETER

temperatures used are far above the range of thermocouples.

Measurements by radiation can be carried out at a distance, once the laws connecting temperature of radiating body and intensity of radiation have been determined, and the radiation-

receiving and measuring part need not be heated to the temperature of the radiating body, nor even anywhere near that temperature. Pyrometers utilizing radiation are divided into two classes, those which measure, as heat energy, the total radiation falling upon the receiving part of the instrument and those known as optical-pyrometers, which are based upon the fact that the luminous radiation of light varies in a definite manner as the temperature of the body changes.

The greatest success has been attained by separating one kind of wave length of radiation, usually that which excites the sensation of red, and comparing the intensity of this one-color light with the intensity of the light of the same color emitted by a standard source of light. The eye is very sensitive when comparing the brightness of two surfaces when one is super-

posed upon the other, and after having arranged to have light from the hot body and light from the standard of comparison viewed in this relation, they can be made equal,

either by varying the amount of light received from the incandescent object, or by varying the intensity of the standard of comparison.

The latter method, that is, variation of the intensity of the standard of comparison, is preferred and used by the U. S. Bureau of Standards, also by the Reichsanstalt, of Berlin, where its practical application has been brought to a high degree of perfection by Holborn and Kurlbaum. The Leeds & Northrup Co., of Philadelphia, working under the fundamental Morse patents, has lately carried on a prolonged investigation and development of this type of optical pyrometer with a view to realizing a high degree of accuracy and reliability in a simple and portable device. The instrument, which is illustrated herewith, is suitable for measuring from dull red (about 1100° F.) up to the highest known temperature.

The manner in which the luminous radiation from the hot body is balanced against that from a standardized source will be understood by reference to the accompanying figure.

*L*, Fig. 1, is a lens by which rays from the hot body at *C* are brought to a focus in the plane *F*, where there is placed a tungsten-lamp filament. By means of the eye-piece *E* the observer views the incandescent-filament, which appears to lie upon the image, just as the cross-hairs in a surveyor's

FIG. 1. OPTICAL SYSTEM AND ELECTRICAL CIRCUIT OF THE LEEDS & NORTHRUP OPTICAL PYROMETER

telescope appear upon the distant object. By means of a rheostat in a case slung about the neck, the case also containing a storage-battery and a milliammeter, the current through the lamp is adjusted until the brightness of the filament is just equal to the brightness of the image produced by the lens, that is, so that the filament blends with, or becomes indistinguishable upon the background formed by the hot object. The observer then notes the reading of the milliammeter, which may be provided either with a special scale to read in degree of temperature, or the temperature corresponding to the current may be read from a calibration-curve supplied with the instrument.

The adjustment is made with great accuracy and certainty, as the effect of radiation upon the eye varies some 20 times faster than does the temperature at 1300°F., and some 14 times faster at 3400°F., while as above stated, the eye is very keen in distinguishing differences in brightness between superposed objects.

At high temperatures the light emitted by both the hot body and the filament would become dazzling, and comparison would be difficult. For this reason a red glass is placed in the eye-piece at *R*, which has the further advantage that light of only one color then reaches the eye and no difficulty is introduced by lack of color identity between the light emitted by the hot body and that emitted by the filament. The intensity of light radiation of any one color increases progressively in a definite

manner as the temperature of the radiating body rises, and nothing is therefore lost by eliminating all other light from the comparison. As only brightness, not color, of light is matched, inability to distinguish colors and color-blindness do not interfere with the use of the instrument. In fact, in the region of temperatures used for hardening steel, for example, different observers using this instrument agree in their readings within 6° F.

The brightness of the image of the hot body produced by the lens *L* is almost absolutely constant, irrespective of the distance from the hot body, although the size of the image varies with the distance. Since it is the brightness of the image and not the total radiation received through the lens that is measured, it is possible to measure the temperature of a small body, or of a body at a distance, equally as well as that of a large body, or of one near at hand. It is not at all necessary that the hot body should fill the entire field of view of the instrument, as with total-radiation pyrometers.

In observing bodies at very high temperatures, as 2500° to 10,000°F., the light received through the lens would be too blinding for direct observation, even through the red glass of the eye-piece, and the intensity of the image might also become greater than that at which it is practicable to burn the tungsten filament, so that a balance would become impossible. Some method for reducing the intensity of the light from the hot body, such as by varying the aperture through which the light is received or by placing a screen to intercept some of the light, is therefore necessary. A screen is used, placed between the lens and the image so that it reduces the light from the hot body, but not that from the filament. With the reducing screen it is possible to make direct observations of the most brilliant light sources, as the electric arc or the surface of the sun.

It is not feasible to calibrate the instrument at such high temperatures by direct comparison, since they are above all known melting points and the ranges of contact-thermometers, but fortunately a relation has been found to exist between temperature and intensity of radiation of any one color or wave-length of light. By making use of this relation, known as Wien's law, and reducing the intensity of the image in a known ratio by means of the screen referred to, it is possible to extend the scale of the instrument to the highest temperature. The scale thus obtained has been found to agree closely with a scale of temperatures established by known facts about the relation between temperature and total radiation. In other words, this form of optical pyrometer gives the same scale of temperature as do total-energy pyrometers used with the precautions necessary to secure accuracy and precision in the measurement of total radiation.

The screen used for cutting off part of the radiation from very hot bodies can be thrown into or out of the field of view by means of a milled-disk projecting through an opening in the tube of the instrument. With the absorbing screen in use, a different milliammeter-scale, or calibration-curve is required, but as the range of the instrument without the absorbing-screen overlaps many hundred degrees with the range for the absorbing-screen, the accuracy of the two scales can always be checked by observing a hot body whose temperature lies within this range.

The readings obtained with this instrument are always the same for the same temperature, if the body viewed is surrounded by other objects, such as the walls of a furnace at the

same temperature. Also, no correction is required in the case of so-called 'black bodies,' such as incandescent carbon, when viewed in the open. For iron and steel in the solid state, the corrections required for readings taken in the open are also negligible.

Objects having a metallic sheen, that is, a surface which reflects light freely, as molten metal, or polished platinum, do not give the same readings when viewed in the open as when viewed in the furnace, or as a black body would give with this, or any other radiation or optical-pyrometer. The readings, however, are always consistent for the same material under the same conditions, and by using suitable reduction factors, can be converted to true temperatures. Furthermore, the readings obtained with this type of instrument when sighted upon a body in the open, differ less from those given for the same body at the same temperature enclosed in a furnace, or for a black body at the same temperature, than do the readings of instruments which measure the total-radiated energy. In other words, the correction where there is a departure from 'black body' conditions is smaller than with the total-radiation pyrometer.

The instrument can be calibrated by sighting it upon bodies whose temperatures are known, either by means of a thermocouple pyrometer, or by the melting or freezing of various substances. The constancy or reliability depends upon the constancy of the lamp, that is, its ability always to shine with the same intensity when receiving the same current. This matter has been investigated exhaustively by the U. S. Bureau of Standards and by the Nela Park laboratory of the National Electric Light Association; also in the laboratory of the Leeds & Northrup Co., and it has been found that after a tungsten-filament is thoroughly aged, that is, burned for some time at a temperature higher than that to which it will be subjected in service, no sensible variation thereafter occurs. The instrument is so designed that one lamp can quickly be replaced by another, and by keeping two lamps, their correctness can always be insured by checking one against the other.

The instrument itself is handy and portable, weighing only a few ounces, and can be sighted as easily as an opera-glass. The case, containing the battery, rheostat, and milliammeter, is designed to be slung about the neck, and weighs about 10 pounds.

### Delay Electric Blasting

In mining operations, especially in tunneling and shaft-sinking, it is necessary to fire the holes in each round in sequence, or rotation, or series of rotations.

The cut-holes are fired first in order to blow out the centre of the breast or bottom, giving a free face for the relief-holes and the rib-top, and lifter-holes, which follow in the order named. A good cut is absolutely essential, for the success of a round depends upon this first relief of the burden upon the succeeding holes. Otherwise, there will be a 'potting-out' or 'boot-legging' of the holes with a consequent loss of dynamite and drilling time.

While fuse and blasting-caps have been used for a long time for all mining work, there is always a possibility of the cut-holes, especially where they point rather closely together, potting into the cavity made by the first hole fired without effectually enlarging the cut. There is also a possibility of the miner becoming hurried where a large number of fuses are to be lighted and his failing to light the whole number, thus breaking the sequence of the round.

Electric firing by means of delay electric blasting-caps will overcome many of the disadvantages connected with rotation firing in mining work. These allow of three series of rotations.

The No. 6 electric blasting-cap (black insulated wires) explodes instantly upon application of the electric current. The first-delay (white insulated wires) follow after a short interval of time; these in turn being followed by the second-delay (blue insulated wires). They can all be used in wet work and under water, which are usually all that is necessary except in large tunnels or shafts.

DELAY ELECTRIC BLASTING-CAPS

METHOD OF CONNECTING A ROUND OF HOLES FOR ELECTRIC FIRING

By using instantaneous electric blasting-caps in the cut-holes, first-delay in the rib-roles and second-delay in the top-holes and lifters, all connected together, the entire round can be conveniently and effectively fired by one application of the current. A slightly different arrangement of the bore-holes is desirable, in that an elongated V-wedge is blown out by the cut-holes. As all of the cut-hole charges are detonated at the same instant each hole aids the other, hence, a smaller amount of dynamite is necessary than with the cap-and-fuse method. The holes loaded with first-delay electric blasting-caps follow the cut-holes after a short interval of time, and these in turn are followed by the second-delay holes.

The advantages of electric firing are numerous. The miner is at a distance in a place of safety when the blasts are fired. Missed holes are practically eliminated. Long-delayed slow-burning holes are done away with. Trouble from wet ground is reduced. The drilling of from one to three holes per round is saved, and consequently a saving is made in dynamite. There is no total or even a part loss of the round by the failure of one hole.

The cut-holes, numbered 1, are loaded with instantaneous electric blasting-caps and fire first. Those numbered 2 contain

first-delay electric blasting-caps and fire second. The holes numbered 3 are loaded with second-delay electric blasting-caps and fire last. Where there is no parting line on the foot-wall, as shown in the cut, the arrangement of the holes would be slightly different to lift the bottom. The wires are all connected in series and fired by a blasting-machine or power-circuit.

### The World's Largest Chimney

The construction of a 570-ft. chimney on a mountain top in a region of Japan that is frequently visited by earthquakes, presents an engineering feat of no mean magnitude. The necessity for intensive cultivation in Japan has made every square foot of soil of economic value to the welfare of the

THE TALLEST CHIMNEY IN THE WORLD

Japanese people, with the result that smelter-fumes are taboo.

The chimney herewith illustrated, which is the highest on earth, was constructed by an American firm, the Weber Chimney Co., of Chicago, employing native Japanese labor exclusively, for the Saganoseki Refining Co., at Saganoseki, Japan, under the supervision of eight Americans. R. H. Steen, president of the Weber company, was personally in charge at the beginning of the work, which was completed under the direction of Charles P. Woodworth, vice-president of the company.

It is 570 ft. high, 42 ft. 8 in. outside diameter at the bottom, with an inside diameter at the top of 26 ft. 3 in. It is designed to withstand earthquake vibrations and has a shell-thickness of 29½ ft. at the bottom and 7 ft. at the top. The reinforced-concrete foundation rests on gravel on top of a mountain. The maximum bearing per square foot, under 100-mile per hour wind-stress, equals 6000 lb. per sq. ft. The thick-

ness of the foundation is 17 ft. The diameter of the foundation is 95 ft., and contains 2711 yd. of concrete. It required 30 days to place this foundation, working 24 hr. daily. The total steel reinforcement in the structure weighs 530 tons and consists of plain round-steel bars and square bars of American make. This steel was purchased in Japan from stock.

The chimney has a reinforced-concrete lining to a height of 150-ft. above the top of the foundation. This lining and shell are separated by a 4-in. air-space.

The cement used was of Japanese manufacture and equal to that of American make. The mixture in the shaft was 1:2½:4; in the foundation, 1:3:5. Two sets of wooden movable forms were used which permitted allowing the forms to remain in place 24 hr. after the concrete had been poured. A Smith mixer and steam-hoist, for mixing and hoisting the concrete, were used.

All the scaffolding was built on the inside, no outside scaffolding whatever being used. The contract was closed in February 1916 and the chimney was completed in December of the same year.

The chimney is situated 2500 ft. from the furnaces and at an elevation 430 ft. above them, and is connected with a flue constructed of reinforced concrete running up the hill-side. The flue is 30 ft. in diameter.

### Commercial Paragraphs

Aall & Co., of Tokyo, the Japanese agents for the AMERICAN STEEL EXPORT Co., has added B. Orum Andresen to its engineering staff. Mr. Andresen, prior to leaving for Japan, spent several days acquainting himself with the organization and the facilities the American Steel Export Co. have for export-engineering and contracting.

The CHICAGO PNEUMATIC TOOL Co., Fisher building, Chicago, has issued a second edition of Bulletin No. 137, which describes and illustrates the Chicago Giant rock-drill, tappet-type. This drill is adapted for use in quarry or underground workings. It was used with excellent results in the tunneling operations on the Catskill aqueduct.

The HARDINGE CONICAL MILL Co. has issued an illustrated catalogue, No. 7, descriptive of the Hardinge conical mill. It presents a large amount of valuable data on the performance of this mill, describes the action of both the ball and pebble-mill, gives operating costs, and makes comparisons with other mills using balls or pebbles in grinding. The book is well illustrated with both half-tones and line drawings. It can be had on application to the Hardinge Conical Mill Co., at 120 Broadway, New York.

The ALLEN CONE Co. of El Paso, Texas, recently placed orders for the Allen cone with the Old Dominion Co., the Shannon Copper Co., the St. Joseph Lead Co., the Arizona Copper Co., the Three R Mining & Milling Co., and the Arizona Ore Reduction Co. The company reports constantly increasing business, but most of the orders received are from the companies already using the Allen cone. The above order from the Old Dominion company was the fifth, that from the Shannon company the fourth, and each of the others were second orders.

Among those in the service of the AMERICAN STEEL EXPORT Co., of New York, who have been called to the colors is K. G. Martin, manager of the service and publicity departments. Mr. Martin was granted an honorable discharge from the 22nd Regiment, Corps of Engineers, N. G. N. Y., to accept a commission as captain, Officers Reserve Corps, motor-transport service. His membership in the American Society of Mechanical Engineers, American Institute of Electrical Engineers, National Electric Light Association, Society of Automobile Engineers, New York Electrical Society, and American Museum of Safety, indicates his wide acquaintance with engineering practice and the knowledge he will be able to bring to bear on military problems.

# EDITORIAL

T. A. RICKARD, Editor

**I**N our last issue we published an excerpt from the brief of the defendant in the Butte & Superior flotation suit. In this issue we give our readers a similar excerpt from the plaintiff's argument in the same case.

**O**N another page we reproduce a note on the cargo of copper that was lost on the 'Pewabic' in 1865. Later information states that 50 tons of copper, valued at \$30,000, has actually been recovered by the divers. We note also that our correspondent at Juneau reports that a diver has contracted to retrieve the high-grade copper ore from the Kennecott mine that has been spilled into the harbor at Cordova in the course of loading the ore during the last three years. He is to be credited with half of the copper he recovers for the company.

**W**E are able to publish an article by Mr. Harold T. Power, who for many years directed the successful operations of the largest drift-mine in California, namely, the combined Hidden Treasure and Mountain Gate, on the Forest Hill divide, in Placer county. The reader may be surprised to learn how much timber is required in this kind of mining. When in full operation the Hidden Treasure mine consumed 2,000,000 feet annually. The tunnel that followed the course of the ancient river-channel, now buried under lava, went through a mountain, from side to side, and was four miles long.

**S**UNDRY smooth gentlemen in New York suggest that a market for Liberty bonds should be created by allowing the tax on excess profit to be paid in large part, say, 60 out of 78%, by purchase of such bonds. This is a lovely bit of spoofery. Mr. Otto H. Kahn has shown that the immunity from income-tax on big incomes, subject to super-tax, will give the  $3\frac{1}{2}\%$  rate of the Liberty bond a yield of 6.45% in respect of incomes of over \$250,000, 8.75% on over \$1,000,000, and 9.21% on over \$2,000,000. In short, the plutocrats made by the War are to evade taxation and obtain a gorgeous income from their excessive profits. It is too thin.

**C**HEMICAL engineers are in demand. The call for men comes from a wide range of industries, many of which are intimately related to metallurgy. The development of wet processes, and the extraordinary growth of electro-chemical applications to the preparation of metallic products for the market, has rapidly narrowed the buffer-zone between the metallurgist and the chemist. Distinction between the two is disappearing; even in ore-dressing the successful practitioner must apply recondite principles of colloid chemistry that lead

also into the utilization of organic substances. It is a pity that it has seemed necessary to call into military service so many young men from the higher classes in our universities. It will leave broken ranks in the recruits of trained technologists that will be needed so urgently if the War should continue for several years. It will also leave us short of young chemico-metallurgic engineers to maintain our industrial expansion after peace has returned. In order to make good the deficiency to some extent young women might be trained for sundry branches of this work, since they have demonstrated special aptitude in laboratory practice, but the response is not likely to be great. The Government would do well to discriminate against the enlistment of young men who are receiving a university education until they have completed their training. To do otherwise is to risk setting the nation back in its provision to meet the problems of the future.

**A**NTIMONY is of peculiar interest, despite the fact that the market has exhibited extraordinary dullness. It is always when antimony is inactive that it pays to prepare for the sudden leaps in price that characterize this metal. When the price jumps it is too late to develop the mine to take advantage of the rise in value. Being a minor metal, with largely fluctuating demand, it is peculiarly liable to erratic quotation. It must be remembered that we are chiefly dependent upon China for our supply, and antimony is just needful enough in our domestic economy to make it a matter of concern to look curiously, not once but repeatedly, at every district on our own continent that is known to contain it in any quantity. Consequently the article on the occurrences in Arkansas, by Professor Ellsworth H. Shriver, in a recent issue, may serve a useful purpose in stimulating search and development. If done by corporations financed so as to be able to tide over depressions in the market, such exploration would appear to offer attractive opportunity. There are other districts that should be searched carefully, one of these being the Tehachapi-San Emidio zone of antimony-mineralization in California. Durango, in Mexico, also possesses notable outcrops that have not received the attention that they merit.

**C**ARRANZA is persistently pressing the Administration at Washington to speed his plans for enjoyment of a portion of the bounty that this country is distributing so freely among the nations pledged to overthrow the common enemy. We have frequently pointed out that his interference with Americans in Mexico was inspired by the definite hope of obtaining money. It may

seem anomalous to our people that anyone should undertake to badger or to injure another as a means for stimulating his generosity, but this indicates how difficult it is for the plain American to comprehend the subtle mind of a Mexican cacique. Carranza is a born psychologist; he knows that kicks constitute the humanly probable response to an appeal for sympathy, and that a war-hating people is more likely to compromise with open purse in hand than to bother about chastising him for his petty annoyances. He fully understands this nation has never taken the Mexican interests of its citizens seriously. The money invested across the Rio Grande seemed small in proportion to the total industries of the country, as in truth it is; therefore he has felt certain that his pestering would not lead to armed reprisals, especially at a time when we were busy with a war of real magnitude. The result has been what we predicted weeks ago: by his interference with our vested interests in Mexico he has called attention anew to his existence and to the possibility that if we do not sustain him he might turn to Germany, which, conceivably, might be to our disadvantage. The scheme has worked so well that the good offices of the Government have been enlisted to the extent of unofficially arranging to send a group of expert accountants, nominally representing New York financial institutions, to study the situation in Mexico with the prospect of accommodating the crafty fox with a loan of \$300,000,000 recently authorized by his validating agents, otherwise known as the Mexican congress.

**D**OUBT as to the ultimate intentions of Japan has been felt by many people in this country; we have wavered between trust in her professions of friendship and suspicion of left-handed dealings with Germany. The Zimmermann episode left something to explain that has not been made perfectly clear to the public mind. Despite assurances that Japan could be depended upon to play fair as a loyal ally, her activities in aiding Mexico in preparation for an independent supply of munitions, and her quick resentment of our kind expressions to China at a moment of crisis, strongly pointed toward ulterior motives. Just what these are has been revealed in a surprisingly frank statement by Mr. Kazan Kayahara, former editor of the *Yorodzu* and of the *Third Empire* in Tokio, but now temporarily in New York as the representative of the Japanese press. The interview was given to *Las Novedades*, the leading Spanish newspaper in the United States, and an aggressive Carranza organ. Mr. Kayahara insists that Japan must have a free hand in China, and that no interference with her supremacy there will be brooked. Japan needs iron and coal from China for the further development of her steel industry, and she proposes to control the Oriental trade in cotton goods. "Only a part of the Japanese nation is disposed to fight because of exclusion," he said, "but this other question of supremacy is one regarding which the whole people thinks as one man. It is a matter of life or death for us. Isolate Japan and you crush her;

but we do not intend to let her be crushed without a struggle. You know that Japan is not without friends in case of a new world-alignment of nations. If the United States, Great Britain, and France press us too hard we will not hesitate to make an alliance with Germany. There exists no hostility against Germany in Japan. In truth the Japanese admire Germany. The greater part of our scientific men have been educated in Germany. Our army has been organized on the German model. Our physicians are almost all graduates of German clinics. There do not exist any anti-German sentiments in Japan, and the events of the War have augmented our admiration for the German people and their government. In case of necessity we would turn naturally toward Germany, and this necessity would arise if the present enemies of Germany should undertake to dispute our supremacy in the Far East, that is to say, in China." After that pronouncement it would seem that we need no longer entertain any doubt as to the limit of strain that may be put upon the Japanese alliance with the warring powers whose cause has also become our own.

## Concrete Ships

The announcement that a reinforced concrete ship was being built in California has attracted general attention. It appeared to be a remarkable innovation, and at first sight somewhat incongruous. As a matter of fact the construction of concrete boats is not new; as long ago as 1899 scows and barges of this material were made by Carlo Gabellini for service on the Tiber, and by 1905 his experience had resulted in the development of that method of boat-building so far as to admit of the construction of 150-ton barges for Civita Vecchia. Gabellini was, however, anticipated by a cement company in Holland that built some small boats in 1887, and gradually ventured upon more pretentious vessels of 50 to 60 tons capacity. Concrete barges are by no means uncommon in this country, the Arundel Sand & Gravel Company of Baltimore having had three such boats of 500 tons each in service for several years, and similar barges were used on the Panama Canal. A pontoon having a displacement of 783 tons was built of concrete for the Sydney Harbor Trust at Sydney, New South Wales, in 1914, and another has made a record on the Welland canal. A sea-going barge of concrete, 210 feet long, was constructed in England about four years ago and towed to South America, where it was equipped as a dredge and has seen hard usage, being subject to the excessive vibration characteristic of this class of work. Numerous patents have been issued in the United States for scows and ships of concrete, but no vessels for navigation on the high seas had so far been attempted until plans for that purpose were perfected in San Francisco. The designs were drawn by Macdonald & Kahn, under advice from the well-known marine architects, Caverley & Garden, the venture being financed by the Standard Oil Company, the Santa Cruz Portland Cement Com-

pany, and some of the strongest capitalists of California. The vessel is being built at Redwood City, on San Francisco bay, and will be ready for launching in about 100 days. It will be 320 feet long, 44 feet beam, and 32 feet molded depth, the hull and strength-deck to be made entirely of reinforced concrete without a steel frame. The net capacity will be slightly more than 5000 tons, and it is estimated to cost approximately \$350,000. In view of the impossibility of obtaining the boilers and engines as soon as the hull will be completed, it is intended to tow it, when finished, to Seattle. This will provide a preliminary test. The Government has already requisitioned the vessel, and others will be constructed as rapidly as possible. The advantage offered by this type of ship is the facility for building more rapidly than when constructing in steel or wood. The limitation to launching a large number of concrete vessels this year lies in the difficulty of securing the necessary power-equipment as fast as needed.

## The Lynching at Butte

On July 31 one of the I. W. W. leaders, a man named Frank Little, conspicuous in the labor agitation at Butte, was taken out of bed and hung by the neck from a trestle. The perpetrators of this crime are not known and no arrests have been made as yet. All good citizens must deplore the act. There should be none so short-sighted as to think that this is the way to get rid of irresponsible agitators and trouble-makers; otherwise our democracy is a failure. We view the event with detestation, not only because it menaces free institutions but because we believe that it does not in the least help to settle the industrial quarrel in the mining districts. Even if it succeeds, for the moment, in terrorizing the ringleaders of the mob that calls itself the I. W. W., it does nothing to check their propaganda; on the contrary, it will breed reprisals similar in kind, bringing the worst elements to the front on the opposing sides of labor and capital. Another blunder was the concession of a 50-cent increase of wages to the miners at Butte. It may cause many of the men to resume work and for a time it may frustrate the plans of the agitators that are responsible for the strike, but it settles nothing. It is a sop to Cerberus; it is a mere palliative that does nothing to cure the disease in the body politic. No principle has been recognized, save that of noise and force. The question of collective bargaining, called the 'union'; the question of the employer's right to discriminate in the selection of his employees, represented by the 'rustler's card'; the problem of participation in profits by the mine-owner and the miner; all these remain where they were, as fertile seeds for future trouble. It is easy to give 50 cents more per day with copper at twice its normal price, but what is to happen when the war-market ceases to support an abnormal quotation? Will the miners accept the logical reduction or is it to be a rule that works one way only? At Leadville also a truce has been declared on the basis of a concession of 50 cents more per shift, leaving the local

food-stuff monopoly to prey on the community, leaving an unscrupulous smelting trust in control of the output, while the question of unionism remains as undecided as before. Of all the ostriches that ever buried their beaks in the sands of time, thinking thus to avoid danger, the worst is the mining industry. We shall not exorcize the demon of unrest either by violence or by bribes. To lynch an agitator or to concede a few cents per day to his followers is no way of settling these vital economic difficulties. Here is where the American Institute of Mining Engineers, daring to become both free and representative, could do a great public service. Here is where the profession, if it were independent, if it did not stand between the greed of the capitalist and the ignorance of the laborer, could guide public opinion effectively so as to stimulate both legislation and government in the right direction. It is useless to close our ears to the questions that must be answered sooner or later, and the sooner the better for all concerned. Has the worker a right to combine for collective bargaining? Has the mine-owner a similar right? Is each restricted to a local combination or may they form extra-territorial organizations, so as to bring secondary pressure to bear on a domestic disagreement? Is a strike no more and no less legal than a lock-out? Has the employer a right to select his employees, as the employees have the privilege of leaving one employer to go to another? Is working by contract beneficial to the individual and the industry? Should a mine-worker participate in the profit of the mine-owner, and, if so, should he accept lower wages when the profit decreases? Should the excessive profit of a mining company go to the workers in that mine or to the State, whose resources are being exploited, or should it all go to the shareholders? Is it fair that a copper-miner should receive \$5.75, while an equally good gold-miner in an adjacent district receives only \$3.50? In short, is the Devil to take the hindmost or is this policy of *laissez faire* to be corrected by a recognition of facts and an effort to make regulations that will square both with them and with the sense of fair play? What we need is a sense of social justice and a deeper interest in conditions that will imperil our social fabric unless we give heed to them. To ignore them is to be ignorant. We invite our readers to state their views.

## Why We Fight

The results of the draft and the imminence of another national bond-issue suggest the necessity for a plain statement of the causes that led the United States to go to war and a clear explanation of the menace against which our armies are being mobilized. The large proportion of exemptions under the draft and the apparent desire of so many vigorous young men to evade military service is a spectacle so ignominious as to provoke anxious thought. We know that the youth of America is neither cowardly nor unpatriotic. Why then is the effort to escape active service so general, and why is it that the parents of these young men have looked around

for excuses or influence to enable their sons to remain at home? The reason is not far to seek; on the contrary, it is so obvious that we marvel why it was not recognized and corrected as soon after April 6 as possible. To our mind an injustice has been done to the youth of this country. For two and a half years the young men were told by the President, and presumably by their parents, to be neutral. This meant that they were not to concern themselves with the great events in Europe, for it goes without saying that a keen interest in such events, and in the underlying causes of them, must lead to a condition of mind in which neutrality would be stultifying. So they took more interest in base-ball matches than in the invasion of Belgium, and were more excited by a Villa raid on Columbus than in the Crown Prince's attempt to conquer Verdun. After the European War—it was only that to them—had lasted two years, they had the chance to elect a new President, and the majority of them—these young men now called upon to shoulder arms—were prompted by their own ideas and by public opinion around them to vote for the President that had 'kept us out of war.' He was elected triumphantly, thereby proving that he had rightly interpreted the wishes and desires of the people of the United States. The President had not begun his second term when the dismissal of the German ambassador made war certain, but even then the peace idea was so strong that our young men still took it for granted that this country could remain detached from the European struggle. Within two months, the President, elected on a peace ticket, turned to the people of the United States with a declaration that he could no longer avoid the arbitrament of war and in the same message he called upon the manhood of America to rally to the flag for a campaign in which the Army and Navy, the capital and the industry, of the country were to be contributed wholeheartedly and without stint in an effort to "make the world safe for democracy." Is it any wonder that the young men were perplexed? Is it surprising that they did not hurry to enlist? Ever since the War began they had been told that it was none of their business, those that volunteered in the French and British armies were scolded, those that remained unperturbed were assured that their own country was not involved in the great catastrophe, that it was our duty to maintain a dignified abstention, and that it was the chief mission of the United States to act as peace-maker between the belligerents. The echoes of these teachings and preachings had hardly died away among the crash of the torpedoes that sank unarmed vessels off the coast of New York when the young men of America were told to make ready for a selective conscription. Do you wonder that they showed no enthusiasm? A large part of them would have volunteered when the call came, but, seeing that they were to be drafted under compulsion, they balked; and when the law allowed excuses to be made, they made them—not without the prompting of parents that had deceived themselves into the notion that this was no war of ours, but one of those cat-and-dog fights for which the Eu-

ropean nations had been preparing so long. So they made a poor response to the President's call to arms. They are not to blame. It is illogical to blame them. We had no right to expect them to make a mental right-about-face until they had been told why the policy of the Government had undergone so sudden a change. They are told that democracy must be made safe. Such abstract ideas are not convincing to everybody. To fight for democracy or against hypocrisy is an intangible issue to the young man rudely awakened from the dreams of peace and plenty. He must be told that he is to fight for his liberty, which is menaced by organized hell; for his country, which is threatened by the navies and armies of a great nation crazed by the lust to conquer; for his home, which may be devastated if things go wrong with those that are fighting the common enemy. It must be made clear to him that if the German armies overcome the Russian resistance, if the Anglo-French attack should waver, or if the German submarine campaign succeeds, then the people of the United States may be held under ransom, then a larger Belgium may be made on this continent by an inhumane and unscrupulous foe, then a German victory over the Allies would involve the surrender of the British navy, leaving the world at the mercy of a power that is without compunction and without shame, a power that bitterly resents first the neutrality and then the hostility of the United States, and that therefore would deal with this country, if it could, in no gentle manner. We fight for democracy and democratic ideas, of course, and the preciousness of this heritage from Washington and Lincoln none of us deny, but we tell every young American that a thousand flags are fluttering in the breeze to signify that we are in a fight for our safety, for the freedom to live and let live, for our hearths and our homes. It is time that all this were told in better words and at greater length to the youth of the country if we are to expect them to show eagerness to serve. Let the two ex-Presidents go on a speaking tour; let such men as Elihu Root and Henry Cabot Lodge be co-opted for the good work; let such leaders of education as President Hibben of Princeton and President Wilbur of Stanford be engaged to explain the great issue; let the diplomats that have returned recently from Europe—Ambassadors Gerard, Penfield, and Van Dyke—tell our people why and wherefore we are committed to this war, and how great is our danger if we wage it unsuccessfully. Then the claims for exemption will become few; then the next draft will have the look more of a great volunteering than a conscription; then at last our young men will go to war with an intelligent idea of the national purpose. Meanwhile, if the President and Secretary of War desire a warmer response to their call, the expeditionary force now in France should go forward into action, as soon as it is ready, not waiting for larger numbers. When American blood has been shed in pitched battle, it will be a summons more eloquent than all the speeches ever spoken. Let us wage this war with a clear understanding of the issue and a keen emotion for the justice of our cause.

# Mining in Utah

By L. O. HOWARD

Difficulties with labor appear to be ended for the present. Outside the strike at the International smelter and allied disputes, none of the troubles became serious. After tying up the plant at Tooele for several weeks, the strikers went back to work the last of June, accepting the offer of a new sliding scale of wages. This provides an increase of 10c. per day for each one cent increase in the price of lead. Eight cents is taken as the basal price, \$2.85 per day being the base for unskilled labor, \$3.80 for semi-skilled, and \$5 for skilled. Before this settlement was made the company tried to get the producers to share part of the increased cost, but this they declined to do. Federal mediators had a large share in arranging a settlement. At the conferences the other smelters and mine operators were represented. A general increase of wages throughout the State was put into effect on July 1. The American Smelting & Refining Co. advanced wages at Murray and Garfield 25c. per day. Mines in the Tintic district posted an increase of 50c. per day. In the Bingham district employees who had received \$3.25 per day will now enjoy an increase of 25c. Those receiving less will have their pay increased 20c. Common labor at the Arthur and Magna mills of the Utah Copper Co. has been advanced 20c., and skilled labor 25c. Operators from Bingham, Park City, Tintic, Cottonwoods, American Fork, Tooele county, and southern Utah, represented in the conference, adopted a uniform scale for different kinds of labor. They will pay machine-men \$4.50, miners \$4.25, shovelers and trammers \$4, and timbermen \$4.50. The Utah chapter of the American Mining Congress was unsuccessful in obtaining a reduction of the insurance rate to be paid under the terms of the Workmen's Compensation Act, which went into effect in July. The rate has been maintained at \$5.59 for metal mines by the State Industrial Commission. No relief from this oppressive rate is in sight. On July 11, the D. & R. G. R. R. announced that it had restored one track to service in Carbon and Emery counties, and was ready to resume hauling coal. Some of the mines are still without transportation facilities, however, and there is a serious shortage of coal at Salt Lake; it arouses fear as to what may happen next winter. Various municipal and state authorities have been investigating the situation. An appeal was made to Washington, and an embargo sought on all shipments over the D. & R. G. except coal. Chairman Willard of the advisory commission of the Council of National Defense has had the question under consideration with the officials of the railroad, and a meeting with the authorities in Utah has been arranged that may result in good. There appears to be plenty of coal at the mines,

but a lack of transportation conveniences, and it is not felt that the railroad is doing all that it might to relieve the situation.

The local United States Assay Office reports an unusual amount of work for this season of the year, an indication of the renewed activity of prospectors. Many assays are made for tin, but so far none has been found in this State.

The Garfield Chemical & Manufacturing Co., which is making sulphuric acid from Garfield smelter smoke, has increased the capacity of its plant to 150 tons of acid per day. A good market for the product is reported, and a still further increase is planned. At Bingham the principal item of interest, outside the continued prosperity of the older mines, is the development undertaken by the Montana-Bingham Consolidated Mines Co. This is a consolidation of the Montana-Bingham, with a 5000-ft. drainage and transportation tunnel; the Tiewaukee, with a record of past production and a good tonnage of milling ore broken; the Valentine, which controls the mineral rights beneath the town of Bingham, and adjoins the Utah Copper mine; the Fortuna, formerly owned by Governor Bamberger, with a record of production of \$800,000, and a large tonnage of ore containing 2% copper blocked out, and a one-fifth interest in the Bingham Amalgamated. A mill employing jigs, tables, and flotation equipment, is in operation, and it is planned to increase it to an ultimate capacity of 1500 tons per day. The mill of the Ohio Copper Co. is treating 2200 tons daily. The flotation plants are handling 600 tons, and will be enlarged at the first opportunity, since the results have exceeded expectations.

Shipments from Park City in July exceeded 7000 tons, although the final figures are not available. June shipments were 6900 tons. The Three Kings mine has been equipped with a new compressor and is pushing development on the 140-ft. level, where the management expects to open the first ore-shoot. To the list of regular shippers have been added the Iowa Copper and the California-Comstock. In the week ended July 27, the former shipped 55 tons and the latter 120. The California-Comstock is equipped with electric and steam plants capable of handling 100 tons per day. There is a mill, 14 years old, but used very little and in good condition. The company owns 135 acres between the Silver King Consolidated and the Silver King Coalition. The ore is netting about \$21 per ton in lead, silver, and zinc. Some of the mine-workings are in copper ore of a good grade. The mine has been opened to the 450-ft. level and is producing 30 tons per day.

Reports from Tintic are encouraging. Among the re-

cent new producers, the Tintic Standard is making rapid progress. Its new 3-compartment shaft has reached the 1300-ft. level. Below 1180 ft. it has been in ore containing about 20% lead and 48 oz. silver. This ore is supposed to be an extension of that from which shipments have been made. The company paid its first dividend in June. Development on the 600-ft. level of the Emerald leads the management to believe that it is near the ore. The mineral so far found has been too low grade to ship, but indications that a better grade lies beneath are not wanting. To investigate this point work has been started on the 1000-ft. level. This mine is believed to be on the extension of the ore-zones of the Grand Central and the Centennial-Eureka. The Eureka Mines and the Godiva, both under the same management, are working in good ore. In June one shipment by the Eureka Mines of 45 tons netted nearly \$40 per ton. This came from the new orebody on the 900-ft. level. Development on this orebody has since increased its known dimensions. Shipments are being made regularly from the 1200-ft. level, and development is going forward on the 1300 and 1400-ft. levels. The Godiva is shipping from the 500, 600, and 700-ft. levels ore that will net \$1500 to \$1700 per car. Work on the 1200-ft. level has cut the same vein, upon which drifts will be started to pick up the ore. The Eureka-Lily has its new electric hoist in operation. The new shaft is nearing the 1400-ft. level, and has entered ground that contains a little metal. The Copper Leaf Mining & Milling Co., adjoining the Tintic Standard, has been equipped for shaft-sinking. The two-compartment shaft was sunk 170 ft. in July to the 200-ft. level. The Iron Blossom paid a dividend of \$50,000 in July, and the Chief Consolidated will pay about \$88,000 early in August; 24 mines are shipping regularly.

The outstanding feature of the Cottonwoods has been the new discovery of ore in the Columbus-Rexall mine, followed by a sensational rise in the shares of that company. On June 30, 13½c. was bid; July 31, sales were made at \$1.55 to \$1.60. The company is a consolidation of the Columbus Extension and the Rexall. For many years the Columbus-Extension has sought the eastward extension of the Toledo fissure, but many engineers have expected it to be found in Rexall ground. Whether it has finally been found is not yet settled. The ore just discovered lies in one of the beds of the limestone. It contains lead, silver, and copper, and early assays indicate a value of \$100 per ton. It has been opened 18 ft. along the strike and is increasing in width. On July 31 it was reported to be 6 ft. wide at the face; 55 tons taken out in development has been shipped, but no returns are yet available. The mine joins the Cardiff on the east and the Kennebec on the south.

In Little Cottonwood, the Michigan-Utah continues to report favorable progress. Settlements in July are lower than usual, but the company has 28 cars of ore in the smelter yards. Ore having a net value of over \$35,000 was shipped in June. One of the lessees has started shipments from an old slime-dump, which, at present high

metal-prices, nets \$10 to \$12 per ton. The Emma Consolidated has shipped about 1800 tons this season. Development is under way to de-limit the orebody. Enough milling ore has been blocked out to induce the management to plan a 100-ton mill. The Sells is shipping 3 cars per week. Transportation facilities have been but little improved. Tramways, teams, motor-trucks, narrow-gauge railway, and standard-gauge railway, all figure in the congestion of ore, and are far from adequate to meet the conditions.

In Big Cottonwood, the Maxfield has resumed operations in a small way under new management. A few shipments of copper ore have been sent out by the Big Cottonwood Coalition, operating at the extreme easterly end of the district. The Cardiff has four trucks hauling about 80 tons per day. The city authorities of Salt Lake have forbidden the use of teams in South Fork, using the authority of a recent ordinance enacted under provisions that allow the control of the water-sheds affecting the city's supply of water. The Cardiff ore has been hauled in teams down South Fork, 2½ miles to Big Cottonwood canyon, where it was transferred to trucks for the haul to the smelter. Only one truck has been found that can make the South Fork grade, and until others can be secured the city has consented to postpone the enforcement of its order.

Production in the Deep Creek region is increasing. The Ferber Copper Co. has shipped 13 cars of ore. The Western Utah Copper Co. is shipping 150 to 250 tons per day. Lessees and smaller operators are gradually increasing the scale of their operations. The Calumet mine in Iron county, although opened to a depth of 75 ft. only, has made an enviable record. It is the first shipper of lead ore from Iron county. The mine is in the new Calumet district, 12 miles north-east of State-line and 35 miles south-west of Frisco. The ore averages 23% lead with a little silver. The first car was sold on September 15, 1916, and the 20th car is now on its way to the smelter. The Antelope Star mine in Millard county has been equipped with a new mill using gravity concentration and K. & K. flotation machines. Expectations that it will become a big producer are high. In the Dry canyon section of the Stockton district five mines are producing. They are the Hidden Treasure, Mono Development, Brooklyn, Utah Queen, and Dry Canyon Consolidated. All are working in good ore. A scarcity of teams and labor greatly hampers the production. It has been necessary heretofore to haul the ore 9½ miles over the divide to Stockton on the main line of the Salt Lake route. The mine-owners have financed a new road down the canyon 4 miles to the Ophir & St. John railroad, which connects with the Salt Lake road at St. John. When this road is completed a larger output is expected.

AVERAGE PRICES during July were: for prime Western spelter, 8.64c.; for zinc-sheet at smelter 19c.; for pig-lead, New York, open market 10.714c., 'trust' market 11c.; electrolytic copper, New York, 28.889 cents.

# Timbering in Deep Placer Mining

By HAROLD T. POWER

The Hidden Treasure gravel mines are situated on the Forest Hill divide in the eastern part of Placer county, California, about 35 miles north-east of Auburn, on the Central Pacific railway.

The deposit is known as a deep lead and consists of white quartz boulders, fine gravel, and sand, lying on and above the slate bedrock, and overlaid by a cap of andesite

quently, namely, the Lee, Mountain Tunnel, and Golden Gate, afterward consolidated under the name of the Mountain Gate placer mine. The operation of this property was handicapped by the fact that mining had to be carried on down-stream, necessitating the driving of successively deeper bedrock tunnels for drainage and the removal of auriferous gravel by gravity. Some members of the Mountain Gate company noted the similarity of the deposits exposed by hydraulic mining at Gas hill,

BREASTING GRAVEL, HIDDEN TREASURE MINE

CROSS-CUT GANGWAY IN THE HIDDEN TREASURE MINE

THE MAIN GANGWAY SHOWING WIDE-SPREADING DRIFT-SETS PLACED TO RESIST PRESSURE OF SWELLING GROUND

agglomerate and tuff varying in depth from 200 to 800 ft. This deposit occupies what was originally the bed of an ancient river, which diagonally crosses the divide that separates the North Fork from the Middle Fork of the American river, its course being nearly north-south. The discovery of this channel-system was made by a Canadian at what was subsequently known as Damascus, on the north or up-stream end. The first mining location was made at the point of discovery and was known as the Canada claim. Other locations were made subse-

and at the Big Gun mine, at Michigan Bluff, five and eight miles respectively from the point of original discovery. After surveys, and tracing of the rim-rock wherever exposed, the conclusion was reached that the channels on opposite sides of the divide were identical, and a tunnel was driven in Blacksmith ravine four miles south from Damascus. The channel was found in place at the extreme south end, where its continuation had been eroded by a more recent stream-system, although no surface indications of its existence were observable at the point of attack, owing to rock-slides and vegetation. This was the beginning of the Hidden Treasure gravel mine, the largest deep-drift mine in the world.

The bedrock of this ancient channel consists of Calaveras slate, which is friable, and when exposed to the air has a tendency to disintegrate, or, as the miners term it, to 'swell.' This gold district is an extension of the Mother Lode of California. The quartz gravel is not cemented, and therefore requires the use of little, if any, powder to break it down. It is obvious that a great quantity of timber would be required to support the roof of such a deposit and to permit the removal of that portion of it containing gold. This river-system has been mined for a distance of about four miles, over a width varying from 200 to 800 ft. The roof of the entire area had to be supported by mine-timbers, spaced from 2½ to 5 ft. apart, which gives an idea of the enormous stumpage that went underground.

The stand of timber in the neighborhood of these mines was greater than that in the mountains of the Sierra Nevada, the average being about 25 M. ft. per acre; that on and about the Hidden Treasure and Mountain Gate properties being especially advantageous for cutting and delivery at these mines.

The principal varieties of timber indigenous to this region that were used in the mining operations, were sugar, white, and pitch-pine, Douglas fir, white and red fir, and cedar. This timber was used for two purposes underground: (1) for the maintenance of the main tunnel; (2) for temporary maintenance while the breasting operations were proceeding.

In the maintenance of the main tunnel sugar pine, Douglas fir, heart of white pine, and red cedar, especially the heart of the last, were found to resist decay to a greater extent than the other species, depending largely upon the moisture conditions in the tunnel where used, and upon the season of the year when the timber was felled—that cut in the fall and winter probably having double the life of that cut during the spring and early summer, when the sap was running. The life of white and red fir and the sap-wood of the white pine was very short where there was little or no moisture from the roof and sides; in many instances lagging 2 in. thick and timbers of 12 in. diam., of these species, had to be removed in less than one year, whereas sugar pine, heart of white pine, Douglas fir, and cedar, under variable conditions, would not have to be replaced in from three to five years. Of course, these conditions were modified by the pressure exerted upon the timbers by what has heretofore been designated as 'swelling ground.' This pressure, in many instances (especially after the ground was first opened) was so great that the timbers and lagging were crushed within a few weeks after setting, necessitating the employment of from two to four crews of timbermen directly behind the miners that were driving the main tunnel ahead. These men had to relieve the pressure on the lagging, set back the timber, and renew those sticks that had been crushed by the so-called 'swelling' of the bedrock. As an example of the action of this swelling bedrock, several instances are on record wherein this formation has been known to rise, or swell, 24 in. within 12 to 15 days, throwing out of align-

ment the T-rail track and the timbers, as well as destroying much lagging and many sets of timber. To overcome the effects of this swelling bedrock, the posts were set at an angle of about 30° from the vertical and 4½ ft. centre to centre, as shown in the accompanying illustration. The reason for setting the timbers at this angle was to relieve them as far as possible from the direct pressure, whereas, if they were set vertically the pressure would be irresistible. See Fig. 1.

The timber necessary in the main tunnel for each complete set was as follows:

2 posts, 12 by 12 in., 8½ ft. long.....	204.0 ft. B.M.
1 cap, 12 by 12 in., 5½ ft. long.....	66.0 " "
35 lagging, 2 by 6 in., 5 ft. long.....	175.0 " "
2 ft. blocks, 14 by 16 in., 4 in. thick.....	12.5 " "
12 cedar keys, 3 by 7 in., 8 in. long.....	14.0 " "
5 bridges, 2 by 6 in., 5 ft. long.....	25.0 " "
	<hr/>
	496.5 " "
5% for wastage .....	24.8 " "
	<hr/>
Total .....	520.3 " "

The 'keys' were made of cedar for the reason that the wood was soft and resilient, and would relieve somewhat the pressure and strain upon the posts and cap, thus preventing, in some measure, their being fractured; when these keys were crushed they could be removed and new ones driven in their place without disturbing the main sets.

After placing the first set of timbers, the lagging is started between the bridges and the main timbers, in the spaces between the keys. To prevent the caving from the top and sides, the lagging is driven ahead as fast as the material in the face is removed. When the lagging is driven about one-half its length a false set is placed to support it until it is driven home the full length. The foot-blocks, posts, and cap are then put in place, the bridges set, the keys driven home between the bridges and the main set, thus taking the weight on the lagging, heretofore supported by the false set. This false set is then removed, and the operation is repeated indefinitely. The timber-crews that follow, to relieve the timber from the swelling bedrock, place what they term centre-sets, thus making each set 2½ ft. centre to centre. These centre-sets are of the same size as the main sets. This gives an idea of the enormous amount of timber required for the maintenance of the main tunnel alone.

I have heretofore stated that sugar pine, Douglas fir, red cedar, and heart of white pine were most suitable for main-tunnel supports; however, there are exceptions to this. Where it is very wet and the ground is heavy, red, white, and Douglas fir have been found preferable to the other woods named. Under these conditions they are not attacked by the fungus growth common to mine timbers. They are resilient, their fibre is tough, and they do not fracture so readily as such brittle woods as sugar-pine and cedar, especially the latter. Therefore, I might say, these woods are invaluable for work of this character, their life being prolonged indefinitely where there is water. The utilization of mine-timber under the con-

CROSS-SECTION ON WORKINGS IN HIDDEN TREASURE MINE

ditions cited is the result of over 55 years experience and close study of the life, adaptability, and best use of timber for underground work.

The removal of the gold-bearing gravel, or 'breasting,' as the miners term it, was performed in this mine as here described. Drifts, or gangways, were driven at right angles from the main tunnel, toward the rim-rock, at intervals of about 200 ft. to the outer limit of the pay-streak, which was ascertained by car-samples washed in the prospect-dump outside. When this limit was reached, what were designated as 'cross-cuts' were driven from

under the caps of each set known as a 'centre-post' further to safeguard the miners. On top of these caps lagging was driven, making a solid wooden roof. In these breasts the posts were at  $2\frac{1}{2}$  ft. centres over the whole area mined. In addition to this it was necessary, if the breasts were wet, to use foot-blocks to prevent the timbers from sinking into the bedrock. It was impossible to remove these timbers owing to the weight which they were compelled to support. As has been stated, breasting was toward the main tunnel, so no effort was made to keep up these breasts except insofar as the immediate safety of the miners required it. However, when water broke through the roof at the face of the breast, it became necessary for safety at that point, to blast down with dynamite the supporting timber some distance back from the face, in order to draw the water and thus relieve the weight on the timber at or near the working-face. All the species of timber mentioned were used in this part of the work, as the life or quality of the timber was not essential. See Fig. 2.

The Hidden Treasure Gravel Mining Co. owned extensive timber-land, and, prior to the creation of the Forest Reserves, miners were permitted to cut timber upon the public domain for their own use without cost or restriction. It was the custom of the company to invite bids for cutting and delivery of mine-timber for underground use for yearly periods. These contracts called for 1,500,000 to 2,000,000 ft. board measure, the dimensions being as shown in the accompanying table.

In early years, when timber was plentiful, there was great wastage in the woods, as only the straight-grained and long-bodied trees were utilized. These trees were 'bucked' into lengths as required, and then split. In fact, I am told that at one time only the finest sugar and white pines were used for making lagging. After the

TIMBERING MAIN TUNNEL, HIDDEN TREASURE MINE

both sides of the gangway, parallel to the main tunnel for a distance of about 100 ft., or, more correctly, 110 ft. up-stream and 90 ft. down-stream along the channel. These gangways were timbered with posts 10 by 10 in. and 6 ft. long, and caps 10 by 10 in. and 5 ft. long, the lagging being  $1\frac{1}{2}$  by 6 in. and 5 ft. long. The cross-cuts and breasts were timbered with posts and caps 8 by 8 in. and 5 ft. long, the lagging being of the same dimensions as that used in the gangways. When breasting commenced, the method of timbering was much the same as in the main tunnel; as the breasting proceeded toward the main tunnel all the boulders and waste were piled back into pillars in the breasted-out portion to assist in supporting the roof. If the ground was heavy, as it usually was, a post and cap of the same size as indicated above was placed under the lagging between each set, designated by the miners as 'gee-becks.' In addition to these sets, it was often necessary to place another post

TIMBERING IN BREASTS, HIDDEN TREASURE MINE

## MAIN-TUNNEL TIMBER AND LAGGING:

Breasting-posts .....	0.12 "
Breasting-caps .....	0.12 "
Gangway and breast-lagging.....	30.00 per 1000 pieces
Foot-blocks .....	0.10 each
Bridges .....	0.03 "

creation of the Tahoe Forest Reserve, when suitable timber to work by this method became more difficult to obtain, the company, in 1905, for ventilation, constructed a double-compartment shaft, 850 ft. deep, to intersect the tunnel at a point more than two miles from its portal. This also greatly facilitated the transportation of mine-timber underground. A saw-mill was erected near the collar of this shaft and thereafter all timber and lumber used by the company was cut at this mill. In this manner there was little waste of standing timber, as the better qualities were sawed into lumber while the tops and slabs were made into mine-timbers and lagging. However, this method increased the cost of mine-timber at the expense of quality, I should say, 25%.

The lumber used in construction work about the mine was purchased from custom-mills in the neighborhood, the price ranging from \$20 to \$40 per thousand according to quality.

Sugar-pine, No. 1 .....	\$40
White pine, No. 1 .....	40
Douglas fir, No. 1.....	35
Sugar-pine, No. 2 .....	30
White pine, No. 2 .....	30
Douglas fir, No. 2 .....	25
Common lumber of all kinds .....	20

The first-class lumber was used for finishing work in and about the buildings, in car construction and repairs, and also in sluice-bottoms. The second-class lumber was used for building-construction, the common lumber for general construction work, sluice-flumes, water-flumes, and track-ties. The lumber used about the mine ranged from 50 M. ft. to 400 M. ft. per year, averaging in cost about \$25 per thousand feet.

The mine-timbers were not treated for their preservation, but by regulating seasonal cutting; and by selection, the life of the timber used underground was materially lengthened. The treatment by creosote, and other methods, tends greatly to reduce its tensile strength, which, in this case, was an important factor in the use of mine-timber by this company.

EXPLOSIVES suitable for coal mining are also adapted to the breaking of ground that is loose and readily shattered by an explosion of a low order of intensity. Such explosives show a rate of detonation of 8000 to 12,000 ft. per second in cartridges of 1½ in. diameter. An explosive capable of a high velocity of detonation develops high temperature and consequently high expansive power, and is more useful for overcoming the cohesion of dense rock. Its power is largely wasted in loose and fissured rock.

## Device for Setting Wagon Tires

The operation of setting a wagon tire in the ordinary way, shrinking it upon the rim by immersion in the blacksmith's slake-tub, is unhandy and has serious disadvantages. As the cooling extends over only a portion of the tire at a time, the shrinking is not uniform, and the operation is so slow that the rim, or a portion of it at least, becomes charred. This charred portion rapidly wears away when the wheel is put into use, causing the tire to again become loose. To overcome these difficulties

the device shown in the accompanying illustration was designed. A pit, 2 ft. deep, is lined with 3-in. plank to make it water-tight, and is fitted with a trap of 2-in. plank. This trap can be raised and lowered by the simple system of levers shown. In the centre of the trap is a hole 1 ft. square, and around it in concentric circles are bored 1-in. holes. The large hole is to accommodate the wheel-hub, permitting the rim to lie flat on the trap; the small holes and the spaces between the planks allow a rapid out-rush of water when the trap is lowered. In using this device the wheel upon which the tire is to be set is placed on the trap. The tire is heated to the required temperature and placed over the wheel. At once the two hand-levers are raised, plunging the wheel into the water. The cooling is uniform and so rapid that charring of the rim is reduced to a minimum; labor and time are also greatly reduced. This device is of great service in blacksmith shops at mines that have much wagon haulage.

PYRITE for sulphuric-acid manufacture, averaging 48 to 52% sulphur, is now selling for 16c. per unit at Atlantic Coast points.

# Formation of Zinc Ferrate

By E. H. HAMILTON, G. MURRAY, and D. McINTOSH

\*Early in the development of the electrolytic method of producing zinc from its ores it was noticed that a large amount of the zinc could be extracted by dilute sulphuric acid, in a few minutes, but that the remainder could be removed only by prolonged boiling. This insolubility was not due, apparently, to the particles of the zinc compounds being protected by the lead sulphate in the calcine, for on removing the lead salt by appropriate methods no increased solubility was obtained. It was noticed, further, that on treating the residue which was insoluble in cold dilute acid with boiling acid, the zinc and iron dissolved approximately in the ratio of one atom of the former to two of the latter. Finally, it was ascertained that a high temperature in roasting increased the amount of insoluble zinc, although the calcine produced might contain less sulphur as sulphide than one made at a lower temperature. The insoluble zinc must be due to the iron, since higher grade zinc ores gave greater percentages of soluble zinc. The lead sulphate has been shown to be innocuous, so that the complexes formed with iron must cause the low extraction. The compounds of zinc and iron oxides have been examined by a number of investigators. Roscoe and Schorlemmer<sup>1</sup> state that Ebelmen obtained black octahedra of the composition  $\text{Fe}_2\text{O}_3 \cdot \text{ZnO}$  by strongly igniting the oxides with boron trioxide. Hofman (Trans. A. I. M. E., 1905) and Wells in the *Engineering and Mining Journal* showed that combination took place between these two oxides, but no attention was paid to the temperature or the time. Ingall's 'Metallurgy of Zinc' (pp. 6 and 32) mentions the formation of zinc ferrite (zinc ferrate).

The results of the present investigations corroborate the observations of Hofman and Wells, and, in addition, go more fully into the conditions governing the combination. The first part of the work consisted of experiments with pure zinc oxide and ferric oxide. Later, some roasting and leaching tests were made on various ores to find out how far the results obtained from the pure compounds applied to the minerals. Ferric oxide was prepared by treating ferric chloride with ammonia and roasting the washed hydroxide for two hours at a red heat. The zinc oxide used was Baker's 'chemically pure.' A mixture was carefully made of material ground to 120 mesh to correspond to the formula  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$ . This was re-ground to bring about an intimate mixture, and the tests were made at the various tem-

peratures in a muffle furnace heated electrically. A thermo-couple, correct at the temperature of melting zinc, indicated the temperatures, and these were maintained constant by varying a resistance in series with the muffle. After the heat-treatment the material was again ground and leached with hot ammonia and ammonium-chloride solution, and the loss in weight found. From these results the amount of zinc oxide that had entered into combination was determined. The tabulated results of tests 1 to 7 are given in table 1, and shown in the curves on plate 1.

TABLE I

6.0	.....	71.2
Experiment No. 7—at 1100°F., no combination took place.		

A few experiments to determine the formula of the compound were made by heating various mixtures so that combination was complete. In all cases where the iron oxide was in excess of the necessary amount for the formula  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$  none of the zinc went into solution. On the other hand, while the results obtained with the zinc oxide in excess did not agree as well as could be desired, it is certain that the compound does not contain more zinc than is shown by the formula  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$ .

TABLE II

Ratio of ZnO to Fe <sub>2</sub> O <sub>3</sub>	Theoretical loss in weight if formula is ZnO . Fe <sub>2</sub> O <sub>3</sub> .	Actual loss.
	%	%
1.5:1 .....	14.4	17.1
2 :1 .....	25.3	20.9
3 :1 .....	40.3	50.9

From the curves it will be seen that the temperature has a great effect on the speed with which the reaction takes place. At 1600°F. the combination is complete at the

\*Bull. Can. Min. Inst., July 1917.

<sup>1</sup>(Page 1225.) The compound is referred to as zinc ferrite, and the name ferrate is reserved for the salt of the hypothetical acid  $\text{H}_2\text{FeO}_4$ . It would seem better to speak of the compounds of ferric oxides as ferrates, and of ferrous oxide as ferrites.

end of one hour. At 1500°F. it is complete in 5 hr. and probably sooner. At 1400°F. the reaction is 85% complete in 3 hr. and complete in 8 hr. At 1300°F. about 70% of the zinc has combined in 1 hr. and 85% in 8 hr., while at 1200°F. it is 4 hr. before the reaction is 70% completed. At 1100°F. no combination could be detected within 8 hours.

Zinc ferrate is a yellowish-brown material, magnetic, and never more basic than  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$ . It is soluble in hydrochloric acid, insoluble in cold dilute  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{SO}_3$ , and hot caustic solutions. It is, however, slowly soluble in hot dilute sulphuric acid. We were unable to find any reagent which would dissolve the zinc without bringing a considerable quantity of iron into solution. During the investigation it was found that zinc oxide also combined with freshly prepared aluminum oxide

PLATE 1. COMBINATION OF ZINC AND IRON AT DIFFERENT TEMPERATURES

made by precipitating aluminum hydroxide from aluminum chloride by ammonia. This was filtered and roasted in a muffle at about 1200°F. for 2 hr. The tests were carried out exactly as with the ferrates. The results were:

TABLE III

Time, hours	Temperature, degrees F.	Zinc combined, %
1	1600	82.2
3	1600	85.3
6	1200	41.0

These results show that compounds analogous to the ferrates are obtained with alumina, but as this investigation was too wide for the time at our disposal nothing further was attempted, as an experiment made with fire-clay and zinc oxide showed practically no combination after 2, 4, and 6 hr. at 1500°F.; so that the alumina in ordinary ores would not combine with the zinc and lower the extraction. The zinc aluminate was insoluble in dilute sulphuric acid.

Ore from the Sullivan mine, Kimberly, B. C., was

roasted at temperatures from 1100° to 1500°F. with hand rabbling. At 1100° and 1200°, however, once the sulphur was ignited it was not possible to keep the temperature down until a large amount of the sulphur had been burned off, so that for a time at any rate the whole body of ore was hotter than the registered temperatures, and the particles on the surface where the oxidation was rapid were at a high temperature for a short time after each rabbling. This is especially noticeable in the upper floors of the Wedge furnaces after the rabble-arm passes; for while the pyrometer in the ore registers only from 1200° to 1300°F. the ore on the surface becomes hot enough to fuse into small balls. The results are seen in

PLATE 2. EXTRACTION OF ZINC AT DIFFERENT TEMPERATURES

table IV and plate 2. The assay of the ore, of which 70% passed through 200-mesh I.M.M. standard, was as follows:

Pb	Fe	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	CaO	S	Zn
13.2	25.3	2.4	2.9	1.4	28.5	22.6

TABLE IV.

Test	Temp. F.	ROAST			EXTRACTION			
		Time hr.	Total S.	S as SO <sub>4</sub>	Zn.	Loss in Weight	Zinc in Tail	Extraction
1	1100	7½	6.95	4.6	23.7	39.1	10.2	74.0
2	1200	4	5.45	4.3	23.0	43.4	9.6	76.1
3	1200	4	6.3	5.4	23.0	38.0	9.2	75.1
4	1300	4½	5.35	4.35	23.0	36.0	10.8	70.6
5	1300	4	4.8	4.4	22.8	29.0	10.3	68.0
6	1400	3½	4.75	4.35	23.6	32.6	12.5	64.4
7	1500	4	5.05	4.31	23.8	27.4	11.5	65.0

In order to test the ferrate theory to see whether a greater percentage of the zinc would be soluble in an ore containing less iron than the ordinary Sullivan zinc ore,

three samples were hand-picked from a carload of the mine shipment before crushing. These samples assayed as follows:

No.	Pb	Fe	Insol.	CaO	S	Zn
1	3.7	11.3	1.0	0.4	31.7	46.2
2	15.2	10.0	0.4	0.3	30.1	41.6
3	10.4	10.4	0.6	0.5	30.8	44.5

These three samples were crushed until 70% would pass a 200-mesh screen and roasted for 4 hr. at a maximum temperature of 1400° + F., and leached. A sample of Sullivan concentrate from the Ding magnetic machine (- 60 mesh + 80), assaying 20% Fe and 27.2%

TABLE VI.

Test No.		Loss in Weight %	Zinc in Tail %	Extraction %
9	Bucked.....	64.8	19.6	84.5

5	Bucked.....	29.0	10.6	66.0
	Unbucked.....	28.8	10.5	68.0
12	Bucked.....	38.7	7.3	84.4
	Unbucked.....	41.9	8.5	82.5

ELECTROLYTIC ZINC DEPARTMENT OF THE TRAIL SMELTER

Zn was also roasted. A good extraction was obtained, as shown in test 12 in table V.

TABLE V.

Sample	Test	Temp	Time hr.	ROAST		Zn.	% Loss in Wgt. in Leaching	Zinc in Tail	Extraction.
				Total S.	S as SO <sub>4</sub>				
1	9	1400	4	5.8	5.4	44.1	64.7	19.2	84.5
2	10	1400	4	3.8	3.6	43.9	50.0	15.9	83.2
3	11	1400	4	5.5	5.3	45.9	62.2	14.2	88.4
4	12 <sup>1</sup>	1400	4	4.8	4.4	28.2	41.9	8.5	82.5

<sup>1</sup> Ding concentrate.

The size of the roasted particles has little or no influence on the extraction. This can be seen by the tests made on bucked and unbucked samples (table VI). The unbucked material was leached as it came from the roaster, while the bucked sample was ground as finely as possible in a mortar.

Roasting and leaching tests were made on other ores and it is interesting to examine the results obtained from these ores in connection with the amount of ferrate formed. The ores treated were as follows:

	Pb %	Fe %	Zn %
(a) .....	trace	7.4	47.6
(b) .....	3.5	15.8	33.0
(c) .....	1.2	6.0	44.0
(d) .....	3.0	6.2	44.2
(e) .....	6.1	4.8	41.0
(f) .....	trace	9.1	45.1
(g) .....	trace	5.3	38.6
(h) .....	trace	9.9	39.9

Leaching tests on these ores are shown in table VII, the temperature being 1400° + F. on a 4-hr. roast.

In this comparison those roasts will be considered that were made for 4 hr. at a temperature of from 1400° to 1500°F. Each unit of iron will combine with 0.58 unit of zinc according to the formula ZnO.Fe<sub>2</sub>O<sub>3</sub> and after 4 hr. at 1400° the reaction will be 90% complete, so

TABLE VII

	ROAST		Zn.	On Leaching Loss in Weight %	Zinc in Tail %	Extraction %
	Total S	S as SO <sub>4</sub>				
a	2.9	2.6	51.6	70.5	16.4	90.6
b	5.7	5.5	35.7	51.5	15.8	78.5
c	7.4	6.8	44.5	69.8	10.7	92.7

h	7.8	7.3	41.5	66.6	12.3	90.1

that we can calculate from the analysis of the ore the amount of zinc that should be insoluble after roasting. Taking 100 gm. of ore as a basis and allowing for the amount of zinc that would probably be present as sulphide and as such insoluble, the results found are tabulated in table VIII.

TABLE VIII

Sample No.	Fe. in ore	Zn. in ore	Zinc with S grams	Insoluble Zn. grams	Theoretical ferrate grams	Difference, grams	Ratio Zn:Fe.	Actual Extraction	Theoretical extraction corrected for Zn combined with S

From an examination of these figures, it will be observed that the amount of insoluble zinc present after roasting is very close to the theoretical amount that should be formed as zinc ferrate with the exception of the regular Sullivan zinc ore (No. 6 and 7) and the magnetic concentrate (No. 12). In each of these instances the ratio of zinc to iron is close to 1 to 1; whereas, in the others, with the exception of one sample, it is at least 4 to 1. In some way, therefore, in these samples, the combination is prevented from being as complete as one should expect from the composition of the ore. One explanation may be that at this concentration of the iron and zinc another compound may be formed containing a greater ratio of iron to zinc than that represented by the formula  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$ , but we have been unable to prove this and regard the existence of any combination except  $\text{ZnO} \cdot \text{Fe}_2\text{O}_3$  as unlikely. On the other hand it may be that free crystals of pyrrhotite do not combine as readily as those crystals which may be attached directly to crystals of blende or as that iron which may be isomorphous with the zinc in the blende. One test made with the addition of 20%  $\text{SiO}_2$  to the Sullivan zinc ore before roasting indicated that the addition of some inert matter decreases the amount of insoluble zinc formed, as an extraction of 76% of the zinc was obtained in this case as against 65% without the addition of the silica. The results of the above test were as follows:

Total S	Roast S as SO <sub>4</sub>	Zinc	Loss in weight	Zinc in tailing	Extraction
3.6	3.2	19.0	34%	6.7%	76.7

One could, of course, determine the effect of adding pyrrhotite or pyrite crystals to the ore by observing whether the extraction were decreased or not, but this has not been attempted, as the results embodied in the present paper, as far as they go, explain the reason for the failure to obtain a high extraction on the ore treated at Trail.

**SUMMARY.** 1. It is proved that zinc oxide and ferric oxide will combine readily at a temperature above 1200° F., the amount combining being dependent principally on the temperature and the time. In the roasting of the ore in the Wedge furnaces, however, in order to desulphurize the ore sufficiently, it is not possible to keep the temperature down to a point at which the formation of ferrate does not occur. In the upper part of the furnace especially, it is difficult to keep the ore from becoming too hot owing to the large amount of sulphur present, but it is possible that, by decreasing the frequency of the rabbling, the ore might be kept for a longer period in the furnace and subjected to a lower temperature, as the more rapid the stirring, while the sulphur is burning readily, the higher the temperature attained. In connection with this, in the case of the Sullivan ore as at present roasted, the maximum amount of ferrate seems to be formed, as some of the regular roast was heated to a temperature of 1500° for 5 hr. and the extraction on this material was no worse than on the original.

2. Free alumina combines with zinc oxide, but when present as a silicate the amount of combination is negligible.

3. There are four ways in which a better extraction of zinc might be obtained from an ore high in iron.

(a) By roasting at a low temperature, the remarks made at the beginning of the summary applying to this point.

(b) By eliminating the iron before roasting.

(c) By the addition of some substance to the ore which would prevent the combination of the two oxides.

(d) By finding some solvent for the zinc that would leave the iron oxide undissolved.

COLLOIDAL particles carry definite electric charges, as is brought out through a study of their precipitation or coagulation. The latter effect is produced by small quantities of electrolytes. The precipitating effect on a negatively charged colloid is dependent on, and increases with, the valency of the positive ion, and the precipitants that are most efficient are those that yield the greatest concentrations of ions at a given dilution. This property is possessed in greater degree by mineral acids than by organic acids. While the precipitation of the negatively charged colloid is dependent on the positive ion of the added electrolyte, the positively charged colloid is influenced mainly by the valency of the negative ion. Divalent negative ions are more effective than the monovalent, for example, barium chloride is more than twice as effective as NaCl added to a ferric hydrate suspension.

# Flotation Tests on Gold Ores

By EDWIN JOYCE

The following tests were made at the State College of Washington on a gold ore from Eagle Creek district, Baker county, Oregon. The ore consists of quartz containing small amounts of pyrite and magnetite. The gold is carried in the quartz as well as in the pyrite, and, as shown by screen-tests, is in such condition that fine grinding is necessary to free the particles. The work was done in a Janney laboratory flotation-machine, using various oils and combinations, with both acid and neutral solutions. On account of the well-known difficulty of assaying high-grade ore, the value of the heading does not always check the value of the combined concentrate and tailing. This may be due in part also to the fact that a few grammes of pulp are almost always lost in the operation of the machine. The following table gives the results of some of the tests:

in test 5, using a special grade of pine-tar creosote, No. 8 G. N. S., 0.019 gm. per drop, was a dry tough froth made up of very large bubbles. On account of the more easily available supply of coal-tar creosote, tests were made to determine its adaptability to the ore, but, when used alone, the results were not satisfactory. The froth was quite fragile and broke down as fast as it was formed, prohibiting any chance of its being collected. A combination of coal-tar creosote containing carbolic acid, No. 22 G. N. S., 0.021 gm. per drop, and special pine-oil, No. 1580 P. T. & T. Co., 0.017 gm. per drop, gave results as shown in tests 7, 12, 13, and 14. A very watery fine-grained froth, in large volume, was produced. The use of 0.5% oil, made in the proportion of 1 part of pine-oil to 5 parts of creosote, was found best suited, the percentage being based on dry ore. As the object was to find the

In test 1, steam-distilled pine-oil No. 5 G. N. S., 0.015 gm. per drop, was used, producing a large volume of coarse lasting froth. This may be compared with the results obtained in No. 2, in which the time was increased, producing a better recovery. The oil used in test 3, crude wood-creosote, No. 400 P. T. & T. Co., 0.02 gm. per drop, produced a smaller quantity of concentrate, but the grade was improved. The froth was smaller in size of bubble and more brittle than that obtained from pine-oil. In test 4, on lower-grade heading crushed to 100 mesh, the same oil gave better recovery than in test 3, showing the effect of finer grinding. The froth obtained

smallest amount of oil required to give good recovery, no tests were run using more than 1% of oil. Test 14 shows the result of decreasing the ratio of water to ore, the recovery falling off; this, however, may be due in part to the manipulation of the machine. In tests 16 and 17 the tailing from previous tests was re-treated and shows plainly that the complete extraction of all the floatable particles was not obtained in the first run. Twenty drops of sulphuric acid was added in each case, but subsequent tests on original ore failed to raise the percentage of extraction when acid was used. No additional oil was necessary when re-treating the tailing, the

same being the case in No. 18 when the concentrate from previous tests was re-treated. In test 17, although not necessary, additional oil was introduced in small quantity. In this case when 10 drops of sulphuric acid was added, the froth appeared in small quantity, and when more creosote was added the froth was killed, appearing again when pine-oil was added, but not in such quantity as in tests 16 and 18. No oil or acid was added when re-treating the concentrate, an abundant, thick, coarse froth forming immediately.

It was found that a combination of sulphuric acid and coal-tar creosote gave an excellent froth, but did not produce as good results as were obtained from a combination of pine-oil and coal-tar creosote. In all cases where sulphuric acid was used it was introduced before the oil, giving better results than when oil was added first. The same result might be obtained by a longer period of agitation, but, as no acid seemed necessary, it was not used in succeeding tests. Examination of the concentrate and tailing revealed the fact that only a part of the magnetite was floated. In the course of the work it was found necessary to replace the worn-out packing around the shaft immediately under the agitating-chamber. As the proper material was not at hand, asbestos-wick packing, covered with hard oil and graphite, was used, and no froth could be obtained in the succeeding test. Upon examination it was found that when the gland-nut was tightened some of the hard oil and graphite had been forced into the agitation-chamber. The lubricant was apparently the source of the trouble, since it disappeared upon cleaning the machine.

In treating ore of this kind, containing only a small amount of sulphide, it is impossible to tell from the appearance of the froth when the maximum recovery has been reached. For this reason it seems best to allow all of the floatable particles to be extracted from the ore in the first operation, re-treating the 'rougher' concentrate, thus forming a high-grade concentrate and a middling that may be subjected to a further treatment.

POTASH extraction from feldspar, according to a statement by Richard K. Meade in *Metallurgical & Chemical Engineering* can be accomplished by mixing one part of ground feldspar, one part of pure limestone, and one-quarter part of calcium chloride, heating in rotary kilns and then leaching the soluble potash compound. This method will effect a recovery of about 55% of the original potash in the crude feldspar. Substituting salt for the chloride of lime gives still higher yields. The recovery varies also directly as the fineness of grinding of the charge. By comminution to a point where 98% will pass a 100-mesh screen the extraction increases to over 70%. Using glauconite-sand, containing 6% of potash, the same process yielded an extraction of 85%. The kiln is heated by direct firing with oil, producer-gas, or pulverized coal, the reaction taking place at temperatures between 800° and 1000°C. This is a lower heat than is required for burning cement-clinker; 250 lb. of pulverized coal per ton of potash-bearing mix is sufficient.

## Molybdenum and Some of Its Uses

There is considerable debate as to whether molybdenum is a benefit to steel and particularly to tool-steel; in fact there is a question as to what use it may be. Some claim that it enhances the value of tool steel, and others deny it. The testimony of steel-makers as to the difficulties experienced in using molybdenum are as follows: Molybdenum tool-steels are said to be likely to crack in quenching, and not to retain their cutting edge after re-treatment, owing to the disappearance of the molybdenum from the outer skin of the steel through volatilization. In some instances tests have shown irregular cutting-speeds and a tendency of the molybdenum to render the tools brittle and weak in their bodies. Again, molybdenum-steel has developed seams and a tendency to fire-crack during treatment. These drawbacks may be overcome or avoided by special care and skill in the preparation of molybdenum-steels high in carbon. Great care is needed also in annealing after the material has been worked into bars, and before it is cut into shapes previous to the hardening. Some of the objectionable features enumerated are due to the use of impure ingredients in the manufacture of the steel or to improper heat-treatment.

In this country, and to a less extent elsewhere, the majority of the manufacturers have almost entirely discontinued the use of molybdenum as a major constituent in tool-steel, and are now using it in a minor capacity in conjunction with tungsten, cobalt, and other rare metals. Iridium-steel and 'stellite' are examples. From 2 to 3% of molybdenum is employed in the manufacture of magnet-steel, and an alloy is also employed in the manufacture of magnet-steel. An alloy containing 2 to 5% molybdenum, 10% chromium, and little or no carbon, is said to be acid-proof or stainless. Elwood Haynes, the inventor of 'stellite,' is quoted as saying that when molybdenum is added to a 15% cobalt-chromium alloy the alloy rapidly hardens as the molybdenum content increases, until, when the molybdenum reaches 40%, the material becomes exceedingly hard and brittle. It cuts keenly and deeply into glass, takes a beautiful polish, which is retained under all conditions, and its surface is not readily scratched. Mr. Haynes predicts a wide application for an alloy containing 25% molybdenum and 15% chrome for the manufacture of fine hard cutlery, but as it cannot be forged the blades would have to be cast. The melting point is not abnormally high.

The principal market for molybdenum in this country is not wide at present. The use of it as an alloy in steel for large gun-linings holds some prospect. The Germans are said to have increased the life of their guns many fold by the use of such a lining. In the steel industry itself in this country there is only a limited use of molybdenum at present. Of course, as a chemical, in the form of ammonium molybdate, it has a wide application in steel laboratories for determining phosphorus in all kinds of steel. It is indispensable for this purpose, but the amount consumed is commercially negligible.

## Launder Flotation Machine

By B. M. SNYDER

The flotation machine illustrated in the accompanying drawings was designed two years ago by George Crerar, flotation metallurgist, and is now in successful use in three mills, including the Comet near Basin, Montana, and the Belmont at Belmont, Nevada. It is similar in principle to the Callow cell, making use of air under pressure forced through canvas or some other porous medium. No heating of the pulp has been found necessary, and in one plant, the pulp has a temperature of about 40° F., due to the cold stream-water used. Recently I re-designed the air-distributors to permit of their being dropped in from the top instead of being attached to the bottom of the cell as in the first machine made. This allows the removal of a distributor for repairs or for changing canvas, without interrupting the operation of the machine. The air-distributors are of cast-iron, with connections for air-pipes and water-discharge pipes. The canvas is held by iron bars which are bolted to the cast-iron pan. It will be seen by inspection of the drawings that the machine is of simple construction, being merely a vat divided into six sections, the pulp flowing through a by-pass from one cell to the other. The drop of three inches from cell to cell gives sufficient hydraulic head to keep the pulp moving freely, and the flat bottoms of the cells permit an even pressure and distribution of air in each individual cell.

The cells are narrow, only 15 in. wide, and in effect the operation of the machine is the same as if the pulp were

run through an aerated launder 15 in. wide and 30 ft. long, baffles being inserted at 5-ft. intervals to check the flow. The narrow width of the cells with launders on either side permits the froth to overflow with a maximum horizontal travel of less than 8 inches. The froth-launders discharge to a main launder, the concentrate being allowed to fill the froth-launder and to make its own slope. A single small spray of water shot down the slope of each launder, under high pressure, is the most effective froth-breaker. The pulp is kept at a depth of 24 in. or less, in the last cell, the tailing-discharge valve being closed sufficiently to allow an overflow in the stand-pipe, thus maintaining a constant pulp-level. A modification of this plan consists in allowing the pulp to overflow a vertical wood-pipe 6 in. square, having a movable gate to raise or lower the pulp-level. The porous bottoms used are 4-ply, 14 to 16-oz. canvas, and they ordinarily last several months before requiring to be changed. In the first machine built, porous brick was tried for use as an air-atomizer, but the varying porosity and the difficulty of maintaining an air-tight joint around the edges of the bricks, compelled their abandonment. The air is regulated by 2-in. globe-valves conveniently placed above the cells, and once these valves are set, a single valve on the main air-pipe can be used to control the frothing.

One man can attend to a number of machines. With this, as with most flotation-machines, regularity of feed, oil, acid (if used), air, pulp-level, and attendance are necessary in order to secure the best results. The cells are of wood and can be built by any good carpenter or millwright. The iron work is largely made up of bolts and standard pipe-fittings, and the air-distributors can

### AIR-DISTRIBUTOR FOR LAUNDER FLOTATION APPARATUS

be made at any foundry. The total cost of a machine erected is about \$450. In addition a positive-pressure blower, capable of supplying air under 5 lb. pressure, is required. The air-consumption will usually not exceed 10 cu. ft. of free air per square foot of frothing-area. The capacity is governed by the amount of mineral to be lifted and can be safely estimated at 250 to 300 lb. of mineral per square foot of frothing-area. This mineral usually requires cleaning in another machine to eliminate the excess of gangue and raise the grade of the concentrate.

As an indication of the results obtained with the machine, the following report of a typical 10 days' run in one plant is given. It should be remembered that the ore treated carried from 0.5% to 1.5% of zinc in the form of a carbonate:

The machine evidently has a field for usefulness and will survive competition unless all pneumatic machines

are superseded by later types, such as the K. & K., that require no blower.

## Magnesite on the Pacific Coast

The development of the magnesite industry has been greatly stimulated by the War. Exports of magnesite from Austria and Greece ceased upon the beginning of hostilities, and investigation of our domestic supply quickly followed. As the War continued the search for magnesite became increasingly eager, until now every available deposit, no matter how remote, is given serious consideration. Roads have been constructed to magnesite deposits situated at long distances from the railroads and the motor-truck has become an important factor in the transportation of this mineral to shipping-points. The first magnesite brought to this country from Greece was imported in the early eighties for use in steel-plants, the amount taken in 1885 being about 500 tons. The yearly totals increased until in 1913 there were imported 175,000 tons of calcined product, representing fully 375,000 tons of crude mineral. Until 1914 the magnesite production of California had not exceeded 10,000 tons per annum. The Porterville district is now exceeding that tonnage every month, according to an official of the American Magnesite Company.

Magnesite is used as a plastic, large quantities being made into flooring, imitation-marble, and stucco, its non-cracking qualities and the hardness of the surface making it especially well suited for these purposes. This branch of the business is yet in its infancy, though magnesite producers anticipate its growth to large proportions when the public better appreciates its possibilities. The calcination of magnesite, through a simple process, is nevertheless interesting. The Porterville Magnesite Co., at Porterville, Tulare county, California, owns one of the most complete calcining-plants in the country, having recently installed at its plant, three miles north-

east of Porterville, the largest rotary kiln in use in the world for the calcining of magnesite. It is 125 ft. long, 7 ft. diam., and weighs 60 tons. It is set in a slightly

MAGNESITE OUTCROP, SAN BENITO COUNTY, CALIFORNIA

MAGNESITE QUARRY, FITCH MINE, STEVENS COUNTY, WASHINGTON. VEIN 80 FT. WIDE

inclined position at the base of what is called Magnesite hill, which is honeycombed with mine workings. The rock is brought from the mine in small mine-cars and dumped into a chute from which it is fed to the plant below. The rock is first crushed to  $\frac{1}{2}$  to  $\frac{3}{4}$ -in. size and is then delivered to the upper end of the kiln. About  $1\frac{1}{2}$  hr. is required for it to pass through. When it issues from the lower end it is thoroughly calcined and has much the appearance of nuggets of gold. The temperature in the kiln is maintained at approximately  $2400^{\circ}\text{F}$ ., the heat being gen-

erated by the combustion of crude-oil, which is preheated in coils of pipe and is atomized by steam as it is sprayed into the kiln at the lower end. The temperature is highest at this end. In the process of calcination pure magnesite is reduced to 52% of its original weight by the elimination of the carbonic-acid. About 1½% iron remains in the calcined material. At some works the carbonic-acid is drawn off and condensed in steel cylinders for distribution to bottling works, soda-fountains, and to chemical plants. This requires a large outlay of capital and the Porterville Magnesite Company does not save its carbonic-acid.

As the calcine drops from the kiln it is carried by conveyors to the cooling-room, and when cool enough is sacked for shipment, although some of it is shipped in bulk. Most of the calcined rock from this plant goes to Eastern makers of refractory bricks and other forms of fire-proof materials. Most of the Eastern buyers prefer that a small amount of CO<sub>2</sub> be left in the rock. Some of the calcine is re-ground to pass a 200-mesh screen. In this form it is used principally in the manufacture of 'sorel' cement for making tile-floors, cement-stucco, and for other purposes, this consisting of calcined magnesite wetted with a solution of magnesium chloride which sets as an extremely strong cement. The rock from the kiln is sampled every 15 minutes and these samples are combined to make a 12-hour average. Each carload shipped bears a certificate of analysis, so that the consumer knows just what grade he is getting. The big kiln of the Porterville Magnesite Co. has been in continuous operation since its installation. Practically all the machinery at the plant is operated by electricity. The time required in re-heating the ordinary kilns when once cooled off, and the increasing demand for magnesite, both crude and calcined, are the primary reasons for employing the continuous-kiln. Other magnesite companies are now adopting rotary calciners, as these have proved more satisfactory than the old upright-kiln.

The magnesite mines at Piedra, in Tulare county, California, are also being developed, and a contract has been made with the Wellman-Lewis Co. of Los Angeles to construct a calcining-plant that will cost approximately \$100,000. This will be only the first unit of a plant that will eventually represent an investment of \$500,000. It is announced that Eastern capitalists have become interested in the magnesite deposits at Piedra and that negotiations have been concluded for the purchase of a large part of the deposits. A plant will be constructed on land belonging to Thomas J. Curran, manager of the calcining plants near Porterville, the machinery now being in transit. This plant also will be of the rotary type and will have a daily capacity of 150 tons of crude rock.

The huge deposits of magnesite in Stevens county, Washington, recently purchased by D. C. Jackling, are proving to be of great importance. One of these masses is estimated to contain not less than 4,000,000 tons of magnesium carbonate. The accompanying illustration shows the Fitch quarry at a place where the mass is

80 ft. wide. In other places it is fully 200 ft. wide. The dump consists wholly of magnesite, and the former owners used to load it into wagons by shoveling from the front of the dump. Under the direction of Mr. Jackling a complete reform will be made in the methods of mining and transportation in order to effect economy in operation. Another mine in the same district, near Chewelah, has been taken over by a San Francisco corporation, the Northwest Magnesite Co., in which S. F. Morse, W. H. Crocker, R. S. Talbot, and B. L. Thane are interested. They are shipping crude rock, and also have a calcining plant in operation. Other operators in the same locality are the American Mineral Production Co. of Chicago, and the U. S. Magnesite Co. of Spokane. The magnesite in these Washington deposits is wholly different in appearance from that commonly mined in California. It is coarsely crystallized, gray to bluish black in color, due to the presence of microscopic scales of graphite. It resembles some varieties of marble or dolomite. It is not dolomite, however, as calcium carbonate is practically absent.

In California, along the Mother Lode, and northward through Placer, Nevada, Sierra, and Plumas counties, are large masses of rock commonly called ankerite; but not all of this rock is ankerite, for frequently no iron or manganese carbonate is present, and the rock then becomes dolomite. When iron, manganese, and calcium carbonate are absent from the rock and only magnesium carbonate remains, the rock must be classed as magnesite, even if it does not conform in physical appearance to the typical magnesite of the text-books. In California these great masses of mixed carbonate, usually, but not always, are associated with serpentine or gabbro; those in Washington are described as occurring at the contact of schist and quartzite. This fact is of no importance, however, as an analysis of the ore reveals, an average sample having been found to contain silica, 0.8%; alumina, 0.4%; iron oxide, 2.7%; lime, 3.3%; magnesium carbonate, 92.1%. In California all the deposits thus far worked, with one exception, occur in association with serpentine. The exception is that near Bissel station on the Santa Fe railroad in San Bernardino county, about 18 miles east of Mojave. There the magnesite is interbedded with shale and thin-bedded limestone. It is possible that some of the great masses of the so-called ankerite of the gold-belt of California may be found on analysis to consist principally of magnesium carbonate. In appearance it greatly resembles the deposits of Stevens county, Washington.

The conical mass shown in one of the accompanying illustrations is a typical outcrop of a large mass of magnesite in serpentine, occurring in San Benito county. It is known as the Sampson mine, and is situated 38 miles west of Mendota, to which place it is hauled for shipment. This is being worked by the John D. Hoff Asbestos Co., of San Francisco.

For use as a refractory material the specifications of the open-hearth steel-makers call for a minimum of 85% MgO, less than 6% SiO<sub>2</sub>, less than 4% CaO, and a loss

on ignition not to exceed 5%. No limit is placed on the iron oxide ( $\text{Fe}_2\text{O}_3$ ) present, although calcined magnesite rarely contains more than 7%. For use in making sord cement and as a filler for paper the silica-content may run as high as 12%. No limit is fixed for  $\text{CaO}$ , while the  $\text{Fe}_2\text{O}_3$  must not fall below 1%.

## A Lost Cargo of Copper

A cargo of copper buried beneath the waters of Lake

those on board 125 persons went to the bottom with her. Like the lost treasure of Captain Kidd, the cargo of the 'Pewabic' has time after time given rise to tales that have brought dreams of wealth. Until now, however, the location of the boat remained a mystery. According to word from Alpena, Benjamin Leavitt, a diver from Toledo, found the 'Pewabic' under 180 ft. of water, and made a confidential report to his fellow adventurers. It is said to have been of such a nature as to induce his backers to lay plans for recovering the million-dollar

ROTARY KILN, PORTERVILLE MAGNESITE CO., IN PROCESS OF ERECTION

Huron since the Civil War probably will soon be raised. Incidentally several residents of Toledo, Ohio, and Alpena, Michigan, hope to get rich through dividing the 'spoils,' which they estimate to be worth, under present war prices, at least \$1,000,000. A diver has located the cargo and Detroit despatches announce that some of the copper already has been recovered. It is declared this is a record in deep water salvage. The effort to recover the valuable cargo revives again the often repeated tale of one of the numerous disasters which help make up the history of the Great Lakes. An August 9, 1865, the steamer 'Pewabic' was bound down from the Keweenaw peninsula with a cargo of copper and a crew and passenger list of more than 125 persons. When seven miles off Thunder Bay island, in Lake Huron, the 'Pewabic' was rammed by the steamer 'Meteor,' and before any of her boats could be launched she went to the bottom. Of

cargo and such other property as may be worth bringing to the surface.—*The Daily Metal Reporter*.

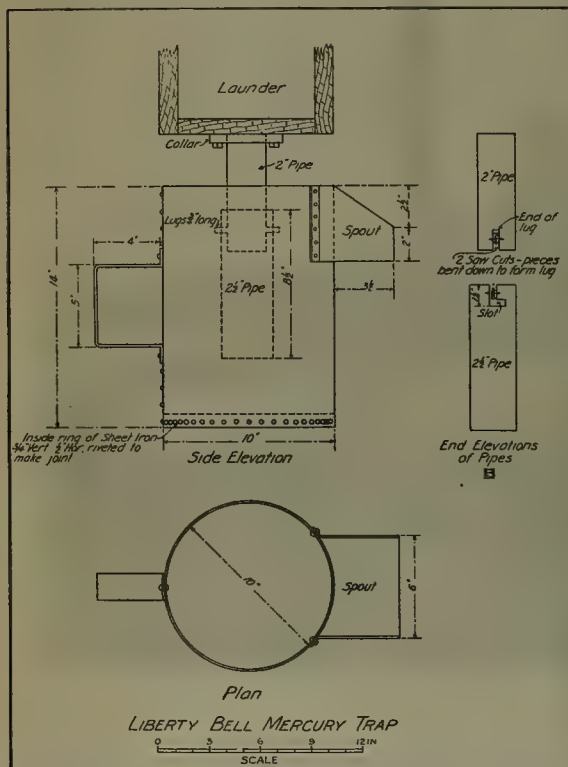

THE DEEPEST American drill-hole is a diamond-drill bore in Sussex county, New Jersey, 4920 ft. deep, recently completed by the contract drilling forces of the Sullivan Machinery Co. A 2-in. diam. core was removed to a depth of 1600 ft., beyond which tools removing a 1½-in. core were used to the completion of the hole. When a depth of 4900 ft. was reached, the long line of rods required for drilling weighed 13 tons, and it took 8 hours' work to hoist, replace, and resume drilling. It is said that the hole showed no deviation from the perpendicular. It required 20 months to complete the hole, which is 1700 ft. deeper than the deepest previous hole of which there is any record in North America.—*Eng. News-Record*.

## Liberty Bell Mercury-Trap

By ALBERT G. WOLF

Mercury-traps involving many variations of the principle of conducting the pulp-flow from plates to the bottom of a receptacle and allowing the flow to discharge over the top have been described. In the accompanying illustration is shown a mercury saver built on this simple principle, which for ease and accessibility in cleaning cannot be equalled. It was used at the Liberty Bell mine, Telluride, Colorado, when amalgamation was practised there.

The receptacle of the trap is made of sheet-iron and is cylindrical in shape, 14 in. high and 10 in. diam. It is

riveted along one seam, and the bottom and side-pieces are held together by rivets through an angle-ring of sheet-iron. This receptacle is fitted with a handle, as shown, and a spout 6 in. wide and  $4\frac{1}{2}$  in. deep, tapering to 2 in. The pulp from the launder at the bottom of the plate is conducted downward through a 2-in. pipe, then through a 2 $\frac{1}{2}$ -in. pipe, 8 $\frac{1}{2}$  in. long, to a point about 4 in. from the bottom of the trap; it then flows out through the spout to another launder. The 2-in. nipple, as it may be called, is threaded at the top and screwed into an iron collar of proper size and tapped out for the purpose; that in turn is fastened to the bottom of the launder by bolts. The nipple is of such length that its lower end will just clear the spout when the trap is pulled forward. Two lugs are formed at the bottom and on opposite sides of the nipple by making two sets of parallel hack-saw

cuts  $\frac{3}{4}$  in. apart and bending the two pieces outward. The piece of 2 $\frac{1}{2}$ -in. pipe is suspended from the lugs by right-angle slots, cut as shown in the diagram at B.

In cleaning the trap, the method pursued at the Liberty Bell mill was as follows: When the pulp-flow had ceased, the 2 $\frac{1}{2}$ -in. pipe was given a short turn and then pushed down from the lugs. The handle of the trap was then seized and the trap pulled forward from under the battery-plate launder. By running a hand down through the pulp just behind the spout, an opening was made to the bottom, and the quicksilver poured out. The trap was as easily returned to its place. Periodically the upper portion of the sand in the trap was skimmed by hand and the lower portion dumped into buckets to be carried to a clean-up pan for grinding. One of these traps was used below each 5-stamp battery of the 80-stamp mill, and a group of seven below the tube-mill plates, or 25 in all. That the conditions under which they worked was severe, and that they did their work satisfactorily is attested by the fact that crushing at this plant was done in cyanide solution, which necessitated the use of a moderate excess of mercury, the total amount used being 50,000 to 60,000 oz. per month in treating approximately 480 tons of ore per day, and the loss for a period of eight months averaged but 2000 oz. per month, or less than 0.15 oz. per ton ore treated. The artificial raising of the temperature of the mill-solution caused an increased loss of mercury of about 25%, undoubtedly due to an increase in the dissolving action of the cyanide-solution. These figures do not include the appreciable saving from pipes, launders, and the like, which could be cleaned only at the semi-annual Christmas and Fourth of July shut-downs. The amalgam saved in the traps varied from 2.5% to 5% by weight of the total amalgam, but was probably of lower grade.

ALASKA is something of a contributor to our much-needed tin demand. Alaska lode-tin was discovered by a geologist of the Geological Survey, while helping two prospectors by crudely smelting in a camp cup a piece of peculiar-looking ore which the prospectors rightly suspected to be tin. Specimens of stream-tin were also collected by Survey geologists in Alaska in 1900, before this metal had been known to occur in the Territory. Prospecting for stream-tin soon became active, and since 1902 nearly 1000 tons of metallic tin has been produced. The output last year was 139 tons. In the Seward Peninsula, where placer tin was first mined, the source of the stream-tin has been discovered and lode mining is now being carried on. Stream-tin is widely distributed in the Hot Springs district, but as yet few of the gold-placer miners make any pretense of saving it. Placer mining in the Hot Springs district can be carried on for about three months in summer.

MT. LASSEN, in California, shows evidence of lava having appeared in the crater within the last few months, though none has overflowed, according to a report by J. S. Diller of the U. S. Geological Survey.

# Fotation—The Butte & Superior Case—III

## Part of Argument by Henry D. Williams, for the Plaintiff

We stand today in this court maintaining that the Supreme Court of the United States has given us a patent for a process identifiable by the results which characterize our process, the air-froth concentrate; and has not imposed upon our patent a limitation which shall be such a limitation that a defendant who puts in 21 pounds of oil, or so-called oil, to the ton of ore, shall be permitted to escape from infringement of our patent, although he obtains the result which we first obtained in the history of metallurgy.

The evidence in the case establishes the fact that there are oils which are frothing-oils; that there are oils which produce the result of the process and they produce it when used in minute and critical proportions. The evidence in the case has established the fact that there are other oils that cannot by any possibility produce the process; they are inert; they are useless for the purpose of producing the process. And the evidence in the case establishes the fact that in the development and improvement of this new art that commenced with the patent in suit, another wonderful discovery was made; the soluble frothing-agent process. That this soluble frothing-agent process, as we demonstrated it, has extreme fineness of air-bubble formation surpassing anything that can be produced by the frothing-oils; and that when you associate together the process of the patent in suit with its critical proportion of frothing-oils, a wasteful quantity of inert oils, and a soluble frothing-agent to prevent the deleterious action or to limit it, of these inert oils, it is possible to carry out the process of the patent in suit in a procedure wherein you pour into the pulp a little more—and a very little more—than twenty pounds of oil to the ton of ore. In fact, these operations have been of exceeding interest. We have found 18 lb. and 19 lb. and 19½ lb. and 20 lb. and 20½ lb., all working the same way, because of this inert oil, and the defendant maintaining that having used more than a fraction of 1% of oil in the ore he has escaped our patent. To that we say that the Supreme Court of the United States has imposed no such limitation upon us. The patent in suit does not impose any such limitation, and the disclaimer that we have filed, following the precise language of the Supreme Court of the United States, has preserved to us—if it be necessary that it should be preserved to us by something more than the other claims—a process wherein the critical proportion of the oils that do the work of the process of the patent in suit are used and additionally an inert oil is poured in in wasteful quantities and a soluble frothing-agent used to prevent it from spoiling the process.

Now, as to the patent in suit. If ever there was a

patent which described the thing that was discovered, this is such a patent. We have the history of the discovery and we have the patent in suit describing it. The first reference in the patent in suit is to two of the Cattermole patents, the principal one 777,273, which is the fundamental Cattermole patent, the other 777,274 merely because it discloses a method of generating oleic acid *in situ*, which is one of the specific things for which there are a few claims in the patent in suit. The patent says: "We have found that if the proportion of oily substance be considerably reduced"—considerably reduced from the Cattermole process, the Cattermole process then being carried out with from 2 to 3 or 4% of oil on the ore—"say to a fraction of 1% on the ore"—not such a close and limiting statement—"granulation ceases to take place, and after vigorous agitation there is a tendency for a part of the oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum."

Then the factors are described as they have been developed in the work in carrying out this process—acidification preferably used—heat also of use. Fine pulverization of the ore not only a factor of the success of the process, but the tremendous advantage of the process, the thing that made it possible to rescue these slimes that had been piled in dumps all over the world and to extract the valuable metal from them.

"The proportion of mineral which floats in the form of froth varies considerably with different ores and different oily substances, and before utilizing the facts above mentioned in the concentration of any particular ore a simple preliminary test is necessary to determine which oily substance yields the proportion of froth or scum desired."

That is the direction to investigate with the means at hand in the laboratory for the purpose of determining what oily substance is best adapted, and in what proportions and under what conditions.

Then follows an example, an example which has been exactly reproduced in evidence in this case, Broken Hill ore. To this is added a mineral-acid or an acid-salt and mine or other waters containing metallic sulphate and it mentions iron sulphate. I think that mine-waters would be apt to contain copper sulphate. "To this is added a very small proportion of oleic acid, say from 0.02 to 0.05%, on the weight of the ore." "The mixture is warmed, say to 30° to 40°C., and is briskly agitated in a cone-mixer, or the like, as in the processes previously cited about 2½ to 10 minutes until the oleic acid has been brought into efficient contact with all the mineral particles in the pulp."

That procedure was exactly followed at the time of the discovery, has been reproduced in evidence in the Hyde case, and it can be reproduced at any time. The amount of oleic acid is also definitely recommended. "The minimum amount of oleic acid which can be used to effect the flotation of the mineral in the form of froth may be under 0.1% of the ore, but this proportion has been found suitable and economical."

Then: "When agitation is stopped a large proportion of the mineral present rises to the surface in the form of a froth or scum, which has derived its power of flotation mainly from the inclusion of air-bubbles introduced into the mass by the agitation, such bubbles or air-films adhering only to the mineral particles which are coated with oleic acid." We have the description there of the froth, oil-coated mineral particles, air-bubbles forming, and froth floating on the surface of the water and carrying a good portion of the metalliferous mineral.

Now, this description, which I have just read, was of the simple operation in the Gabbett, and it is a full disclosure, because the Gabbett was a well-known contrivance as we proved beyond question, although its use under such conditions as we used it in our process commenced with the Cattermole investigation. For Cattermole it was used up to 900 r.p.m. and when thus speeded up it became a really efficient aerator, although in the Cattermole process the air, if it worked at all, worked against the process. Still, it didn't seem to make any difference for the reason that metallic particles coated with oleic acid in the Cattermole proportions 2, 3, or 4% reject air-bubbles, have no attachment that is worthy of the name to air-bubbles. Putting aside all finer scientific questions as to whether it is directly attached or oil attached, they don't stick. The air rushes through in great quantities. It comes in and goes out, and the Cattermole granules maintain their integrity and their tendency to sink, and they do sink the minute you give them a chance against an up-current which carries away the sand.

Now, this description closes with the statement that the froth is removed from the pulp by spitzkast, upcast, skimming, draining, or otherwise. There is a complete disclosure of the process.

Now, the patentees might have rested upon that disclosure, but they went ahead and described an apparatus adapted to the conditions which existed in the art at that day and was a very useful apparatus, because in the art at that day 40-mesh crushing was fine crushing; because in the art at that day they feared to crush finer, because the finer they crushed the greater the proportion of slimes, and the greater amount of the metal that was wasted. Adapted to the conditions of that day, they produced a spitzkasten-classifier for the purpose of classifying their gangue and with it some particles of the mineral and especially the heavier particles of the mineral which were too heavy to be carried in the froth because, as appeared in the evidence here, it was a very serious problem in those days whether it was going to pay to crush the ore to such a degree of fineness as was necessary

for the full realization of the air-froth flotation process.

A wholly new field was opened up in the metallurgical art by this process, and the inventors had not the courage to predict absolutely that such fine crushing as now characterizes the art would be feasible or possible. But with the coarser crushing, of course, the heavier particles would drop out of the froth, and they would have to be recovered by other means, and so there was the spitzkasten-classifier, such as the art knew, combined with the agitating-vessel, and the froth overflowed and the sinking products were classified, and while the particular recommendation was further treatment by agitation—in other words, doing the process over again—there was a suggestion of treatment on a shaking table, such as the art then knew, and there was also a suggestion of another method of treatment, which leads in the art in the agitation by aeration feature which now characterizes what are known as the pneumatic cells. In that method the pulp was subjected to a pressure of air or other gas of one or two atmospheres in a vessel, the result being that the air or other gas went into solution in the water, and then on release of the pressure "the gas was generated throughout the mass at once, sweeping to the surface thereof all the metalliferous matter in the form of a froth, which can be separated as before." That is the pneumatic operation, such as is carried on in the air-basket or the Callow cells, or in the Janney machine which has the air-basket in the spitzkasten.

THE COURT: Is that in the patent in suit?

MR. WILLIAMS: That is in the patent in suit. We had no occasion to refer to it in the Hyde case, because the art had not then found out how to use it.

MR. SHERIDAN: You don't mean it is claimed in the patent in suit?

MR. WILLIAMS: I say it is fully within the claims. Judge Bradford found it to be, and we are waiting for the Circuit Court of Appeals for the Third Circuit. In that language you have the sweeping to the surface of the particles of froth by air-bubbles rising upward, agitation by aeration, which was disclosed in this patent to the metallurgical art, and has now been utilized. That was the particular contention in the Wilmington suit.

Again I read from the patent, still describing this method which was called super-aeration or plus pressure; that is to say, you work at a pressure greater than the atmosphere, and the aeration is the result of relief from that high pressure.

"The whole of the mineral to which the air-bubbles are attached—say the oiled mineral—at once rises to the surface as a coherent scum or froth."

That follows the condition where you relieve the pressure and these air-bubbles come rushing up, sweeping to the surface—a sort of air upcast—or instead of relying wholly on the buoyancy of the air-bubbles to rise, you may start them up by a pressure from below, and by that pressure and buoyancy you get the agitating effect of these bubbles of air rushing through the pulp and bringing the air in contact with all the metal-bubbles, and carrying them to the surface in the form of a froth,

a rather active froth as compared with the quiescent froth which occurs when you have not this pneumatic action.

Now, briefly as to the claims.

Claim 1. "The herein described process of concentrating ores which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of 1% on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth and separating the froth from the remainder by flotation."

There is no limitation as to the means whereby that agitation is effected, as to whether it shall be effected by stirring it violently or whether it shall be effected by shooting air into it. This was the language of Judge McPherson at the argument; he said, "the question is whether you shoot it in or draw it in." The claim merely says, "Agitating the mixture until the oil-coated mineral matter forms into a froth." Agitation, whether mechanical or pneumatic, produces that froth.

Claim 2 adds acidification, which the defendant has used.

Claim 3 adds warming the mixture, which the defendant is not now using, but used up to a comparatively recent time. It uses great care now, apparently, not to warm the mixture, although the oil is warmed.

Claim 5:

THE COURT: Your claims leave it optional, do they not?

MR. WILLIAMS: Yes, claim 1 omits all reference to heating and acidification, and therefore claim 1 is infringed when they operate in the cold and without acid.

Claim 2 includes acidification and therefore claim 2 is not infringed if you omit acidification, if you omit the acid.

THE COURT: Don't you leave acid and heat optional altogether, although approved?

MR. WILLIAMS: Why, it is true as to the broad claims, claims 1, 9, and 12, of the invention, there pointed out, that those claims leave heat and acid as wholly optional, but it is true as to claims 2, 6, and 11 that the invention which is pointed out in those claims includes as an essential part of the invention the use of acid, and it is true as to claim 3 and other claims of the invention, that the invention pointed out in those claims is not infringed if the defendant does not heat the mixture, but uses the cold pulp and omits acid; that is to say, as to those claims, in the one case acid is an essential of the invention pointed out, and in the other case acid and heat are essentials of the invention pointed out.

THE COURT: As a matter of fact if they did not use the other features of your claims, merely using acid and heat, it would not be infringed.

MR. WILLIAMS: Oh, no.

THE COURT: But if they do use the other features of your invention, the mere omission of acid and heat would still leave it infringing?

MR. WILLIAMS: Yes, infringing.

THE COURT: In other words, your patent does not monopolize and limit you merely in the use of acid and heat?

MR. WILLIAMS: Yes. Your Honor gave some consideration to that in your opinion and the fundamental fact is that acid and heat are simply added on to the essential process in certain claims.

Now, that brings us to claims 9, 10, and 11. Claim 9 is the broadest claim in the patent. I will read it as it is in the patent, and then we will consider what the disclaimer has done to it to save it from the criticism of the Supreme Court of the United States.

"The process of concentrating powdered ore, which consists in separating the mineral from the gangue by coating the mineral with oil in water containing a small quantity of oil, agitating the mixture to form a froth, and separating the froth."

Now, your Honor will see that that language as it is drawn exactly describes every operation that the defendant has carried on; that the term "a small quantity of oil" cannot by any possibility be held to be definitive of a quantity of oil wherein we shall stop at 1% and say—above that you are free to use it; below that you must not use it. But of course the term "a small quantity" is indefinite, and the Supreme Court said it was indefinite.

THE COURT: Of course, we must take it as the Supreme Court says. Aren't there other patents where that term has been allowed?

MR. WILLIAMS: Oh yes; the circumstances of the case have to be considered. The circumstances considered by the Supreme Court of the United States was that here was Kirby, with 25% of oil. Now 25% of oil, as compared with Elmore, was small, but it would hardly be considered a small quantity. But the circumstances of the case, the Supreme Court said, were such that your step is not a very long one, from 25%, we will say, to a fraction of 1%. Then there was the Froment test-tube disclosure where 12½% was used; comparing that to a fraction of 1% it is not a very long step. Now, the Supreme Court gave us the identifying characteristics which it would have been very difficult to write into that claim originally. I don't know just what language I would have used had I drawn the claim. The Supreme Court said "The patent must be confined to the results obtained by the use of the critical amount, a fraction of 1% of oil." Now, we have written that limitation into that claim, and wherever we find a process wherein a frothing-oil is at work, in minute quantities, producing the froth of the patent in suit, and when we see that the operation of the process as a whole produces that result which the Supreme Court says is the identifying characteristic of our process—then, under claim 9, as validated by the disclaimer, it is only necessary to consider whether or not the defendant is using a small quantity of oil.

THE COURT: I don't believe I understand you very clearly there. Would it still be infringed if it was more than 1%?

MR. WILLIAMS: If the amount of oil fed into the mixture exceeds 1%—if the amount of oil dumped into the pulp exceeds 1% is 21 lb. or 20.1 lb., or 20 lb., because 20 lb. is more than a fraction of 1%—if the amount of oil dumped into the pulp is 20 lb., and if we find upon examination that 18 lb. of that oil is an inert, useless oil—and Mr. Thomas Janney admitted that these fuel-oils and kerosene-oils—I think his was a fuel-oil—were inert oils that were not frothing-oils at all—if you dumped 18 lb. of a non-frothing oil into the pulp and 2 lb. of an oil that is a frothing-oil, and if you utilize the further discoveries of the plaintiff and put in a soluble frothing-agent so as to prevent that inert oil from spoiling the process, you have carried out the process of the patent in suit. You get the result of the process of the patent in suit, and by grace of the Supreme Court of the United States, when you obtain the results of the process of the patent in suit you use the invention of the patent in suit.

Now, your Honor asked if the words “a small quantity” did not appear in claims; they do. They appear in the claims of our solution patent, which is in evidence.

THE COURT: Of course I had reference to claims that had been upheld in the Supreme Court. I had in mind the Tilghman-Proctor case, where any degree of heat was held to be within the claim.

MR. WILLIAMS: It all depends on the circumstances of the case. Here we have a patent which has been upheld by Judge Bradford, and which we hope will be upheld by the Circuit Court of Appeals of the Third Circuit, and which we hope will not go further. Here is the claim:

“Mixing the ore with water containing in solution a small quantity of a mineral frothing agent.”

There you see the characteristic is that the pulp has dissolved in it a mineral-frothing agent, and the quantity of the mineral-frothing agent is a small quantity. Now, the fact is, as has been testified here, that you can increase or diminish the amount of that frothing-agent in solution within the limits of its solubility, practically, that is, of course you have to have enough to get an action, but a very minute amount has a very wonderful action, and so that claim says “a small quantity,” and Judge Bradford has found that claim to be valid and infringed, and without any question indefiniteness in claims within the permissive indefiniteness that the art permits is a perfectly proper characteristic of a claim. Of course you must not—I cannot quote any better language than the language of the Supreme Court of the United States: “The patent must be confined to the results obtained by the use of a fraction of 1% of oil.” That is what the Supreme Court gave us.

THE COURT: Of course that claim itself is indefinite and allows for the use of a quantity from the smallest to the largest fraction of 1%.

MR. WILLIAMS: Yes, it does; and that range, without any doubt, will take care of the fact that the critical proportions vary with different ores and with different oils. We have not pursued that to its uttermost. For instance, we find that at the Timber Butte mill they have

an ore which is very nearly the same as the defendant's ore, which is being treated with 0.7 of a pound of pine-oil. That is a frothing-agent which has a peculiarity in that it contains the oily or insoluble frothing-agent and a soluble frothing-agent, and the two processes work together there, and the total amount of the oil used is only seven-tenths of a pound. It comes pretty near to being the smallest amount that has been used.

Eucalyptus oil of the Australian variety, according to the evidence, has been used in as small an amount as half a pound to the ton of ore. That is another of those essential oils, which has a soluble and an insoluble frothing-agent in its make-up. The defendant uses pine-oil. Pine-oil is the basis of its whole operation. Pine-oil produces the carrying out of the process of the patent in suit with the critical proportion far below the limit of the largest fraction of 1%. Pine-oil supplies a soluble frothing-agent which gives that extremely minute emulsion which your Honor saw projected on the screen. Additional to that pine-oil they pour in great quantities of petroleum-oils that are not frothing-agents at all; they are inert and useless in the process; they do not contribute to the carrying out of the process at all. And even as to that, they have to be very, very careful. They run up a little above 20 lb. now and then, but the greater part of their operations have been below 20 lb. They get diminished recoveries, diminished grade. They are losing \$100,000 a month, but by this combination they can carry on our process, they can produce our results, they can run their mine, but they are certainly using our invention.

DISSOCIATION-PRESSURES of metalliferous sulphides at comparatively high temperatures, where mercury gauges cannot be used, have been determined successfully by a new method devised and tested by E. T. Allen and Robert H. Lombard at the Geophysical Laboratory at Washington, in conjunction with the secondary enrichment investigation. The method is based upon balancing the dissociation-pressure by a known vapor-pressure of liquid sulphur. Determinations were made on the dissociation-pressures of covellite and pyrite, obtaining the figures respectively of 1 mm. to 500 mm. in terms of mercury. The method applies to other compounds where a single volatile dissociation-product is obtained which does not attack glass and which condenses at temperatures below 1200°C.

SULPHUR is readily soluble in petroleum. Some of the Texas oil contains free sulphur in solution in addition to compounds of that element. In the heavier hydro-carbon compounds the solution of sulphur takes place immediately, even at ordinary temperatures. According to H. Endemann, heavy hydro-carbons react with pyrite also. half of the sulphur being taken up, reducing the pyrite to the mono-sulphide, FeS. The sulphur in oils, as shown by G. Sherburne Rogers, is present in a variety of compounds, some of which are quite complex, but free sulphur is often found in them.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## McCARTHY, ALASKA

**THE STRIKE AT THE KENNECOTT MINE DECLARED BROKEN.—SUCCESSFUL HYDRAULICKING ON CHITITU CREEK.—NEW COPPER PROPERTY BEING DEVELOPED ON HIDDEN CREEK.**

The strikers from the Kennecott mines are dispersing and it is conceded that the strike is broken. The last offer made by the company was a raise in the bonus which would give the men \$5.50 per day with the price of copper above 27½ cents. The men still demanded a raise in the base wage to \$5.75 but finally voted to return to work on the company's terms, pending the arrival of a mediator who is on his way from Washington. The company refused to take them all back, reserving the right to reject any individual. On this point they deadlocked again. The company then started to bring in men from Anchorage and are now about 60% full handed. Ore shipments have been resumed and it is expected they will be normal within a week. On Chititu creek, Frank Kernan is operating his hydraulic plant on No. 11 at the confluence of White and Rex gulches. There is plenty of water this year. About 2500 cu. yd. of gravel is being handled daily with two 3-in. nozzles on the bank, and a 5-in. nozzle for stacking tailing. He has plenty of water for these lines under a 400-ft. vertical head. The gravel bank is 10 ft. thick, which, with two feet of the soft shale bedrock, is piped into the flume. The ground averages about \$1 per cubic yard.

Under the direction of W. H. Seagrave, consulting engineer, the Tjosevig-Kennecott Co., at McCarthy, has commenced systematic prospecting and development on the property at the head of Hidden creek, across the Kennecott glacier from the Bonanza mine.

Work was commenced on a 13-mile wagon-road from McCarthy to the property, but has been discontinued while the more important work of developing ore progresses during the favorable summer months.

Considerable prospecting and some development work in various localities is being done along the limestone-greenstone contact for miles on either side of the Bonanza mine this summer.

## MAYER, ARIZONA

**DEVELOPMENT OF OLD AND NEW MINES STIMULATED BY THE IMMEDIATE PROSPECT OF A MUCH-NEEDED RAILROAD.—MUCH SHIPPING ORE AVAILABLE IN THE DISTRICT ABOUT TURKEY.**

John Slack, of Mayer, general manager for the Fairview Gold & Copper Mining Co., announces that extensive development of the company's property is about to begin. A gasoline hoist has been delivered at the mine and a shaft is to be sunk on a big outcrop of copper, silver, and gold ore which is traceable to Copper mountain. The mine is two miles east of Turkey. The company is fully financed. The officers are: president, F. N. Bonini, of Niles, Michigan; vice-president, W. Miller, of Kansas City; secretary and treasurer, H. M. Coffman, of South Bend, Indiana. This property has one of the largest veins of milling ore on the belt.

Negotiations are under way for the purchase of the old Parker and Great Republic mines in the Turkey district. There are a number of veins that will run high in copper and gold. A 5-stamp mill with cyanide annex is on the Parker property. The Pickaway mine, situated between the Parker and the Great Republic mines, is included in the deal.

James Cleator, who owns the Turkey Gopher mine, and several other claims on which the town of Turkey is situated, expects to close a deal with Los Angeles people for the sale of its property. The development consists of several shafts and adits in a good grade of gold ore. Turkey will be the junction point of two railroads.

The new railroad will open up the district south and east of Turkey where a number of mines have been developed up to the shipping stage, but owing to the cost of transportation

STRIKING MINERS AT M'CARTHY, ALASKA. NOTE THE FLAG

heretofore, the mines have neither been worked nor equipped.

A contract is about to be let by the Big Chief Copper Co. for the sinking of a 500-ft. shaft on one of its properties on the belt between Mayer and New River. A year ago, Jordan and Grace, of Phoenix, secured a large block of mining ground on Black canyon, a mile and a half south-west of Bumblebee, and began development which determined the extent of the several veins of copper and gold ore. A shaft was sunk 50 ft. at the south end in the centre of a mineralized zone 300 ft. wide. It is estimated that 100,000 tons of milling ore can be quarried to the depth of the shaft. Some of the ore is copper glance. On another claim an adit has been run in 250 ft. which has tapped a vein lying next to an iron dike, which can be traced throughout the entire belt. Three veins have been cut which carry a milling grade of ore. In another shaft, at the north end of the property, is found gold ore running as high as \$300 per ton. The officers of the company are: president, Thomas Boyd, of Mound City, Illinois; vice-president, R. E. Grace, of Phoenix; and secretary and treasurer, S. E. Jordan, of Phoenix. This will be one of the first mines to supply ore to the new railroad.

The veins which have been proved on the Big Copper Chief Co.'s ground extend north and south, and three groups of claims have been acquired by Proctor Ross and associates, of

Phoenix. They own 500 acres and plans are under way to develop them. Jasper N. Nellis, who owns an interest in all of these properties, was the original locator.

The old stage camp of Cañon will become important as the new railroad will cross the Agua Fria not far below the town. W. Jeff Martin owns several copper and gold mines in that vicinity. He recently made an important strike of copper on one of his claims, two miles north of the station.

The Kay mine is developed by several shafts along the strike of the vein for a mile and a quarter. The deepest shaft is 350 ft. The vein, small at the start, has opened out to 16 ft. at the bottom and will average 15% copper and enough gold to pay charges of mining and milling. A mile north of this shaft, another has been sunk 195 ft. on the same vein and has developed 8 ft. of ore of nearly as good a grade. The mine is owned principally by S. J. Tribolet, of Phoenix, who has spent \$75,000 in its development.

The Palo Verde is one of five mines that are to be developed by E. H. Wilson, managing director of the new railway company. Recently a contract was let for sinking the old shaft at the Palo Verde another 250 ft. At the bottom of an 185-ft. shaft, the vein is 8 ft. wide and shipments of ore have run 18% copper, 11 oz. silver, and \$22 in gold per ton. The other four mines are the Leland, Senia Raey, Minnie Lee, and National Amalgamated. J. M. Sweatman and C. S. Scott, of Phoenix, are also interested in these five mines, all of which have extensive development.

The Orizaba Mining Co. has been organized to take over and further develop the Orizaba copper mine which is located south-east of the Kay mine about six miles. The officers are: president, George F. Wilson, of Globe; vice-president, Parker Woodman, of Bisbee; secretary and treasurer, A. F. Muter, of Phoenix; W. W. Searles, of San Diego, J. F. Cleaveland, of Phoenix, F. M. Huddleston, of Los Angeles, and T. J. Lawrence, of Pittsburg, also are interested. It is estimated there is 15,000 tons of 7% copper ore blocked out. There are several shafts and adits, all in shipping ore.

### CRIPPLE CREEK, COLORADO

IMPORTANT SURFACE DISCOVERIES CONTINUE.—LESSEES SENDING THE USUAL AMOUNT OF ORE TO THE MILLS.—OUTPUT OF THE DISTRICT FOR JULY.—THE CRESSON COMPANY SHIPS ORE UNDER ARMED GUARD.

The aerial-tram of the Granite Gold Mining Co. from the Dillon mine to the loading-station in the yard of the Midland Terminal Railroad Co., at Victor, is in operation, and two cars have been loaded each day this week. The Dillon mine is operated on company account and making a heavy production.

A surface discovery has been made on the Deerhorn, one of the Globe Hill properties of Stratton's Cripple Creek Mining & Development Co., by Mr. Reynold, a watchman for the company at the Winfield offices on Globe hill. Reynold has employed his spare time in prospecting near by, and discovered a vein near surface from which the first carload, mined at a depth of 12 ft. and shipped to the Portland mill at Colorado Springs, brought settlement at the rate of about \$16 per ton.

The El Paso Extension Corporation of West Virginia, owning the Rocky Mountain and North Slope claims on the south-west slope of Beacon hill, and part of the Nellie Bly adjacent, recently commenced work. Al Campbell, a lease-operator and a former superintendent of the Gold Dollar Consolidated Mining Co., is in charge of operations. Campbell is prospecting at surface and has found rich float, and is trenching for its source.

Lessees on the Little May and Blanche fractions on the east slope of Bull cliffs, adjoining the old Victor mine, have opened up mill ore, and are getting out a shipment by windlass. A steam or electric hoist will be installed if a profit is shown by returns.

The Copper King, a patented claim on the south-east slope of Grouse mountain, idle for years, has been leased by M. Ledgerwood and B. W. Johnson, of Victor. At a depth of 41 ft. the lessees, who are old timers, after cleaning out the shaft, found exposed a narrow seam of quartz that has widened out to about eight inches and carries fair silver and low gold content. They are sinking the shaft and at 50 ft. will prospect the vein by drifts.

Lessees on the Hiawatha on the south slope of Beacon hill have opened up a new orebody and loaded out their initial shipment the first of the week. The ore is silicified granite carrying sylvanite and is returning assays as high as \$45 per ton. Notices have been mailed stockholders of the Blue Flag Gold Mining Co. of the annual stockholders meeting for the election of directors, to be held at the office of the company in the Exchange building, Denver, on Tuesday, August 14. The company owns the Blue Flag mine and mill on Raven hill in this district, now inactive, and properties near Breckenridge, in Summit county, and placer ground in California.

The Neville mill, a cyanide plant situated on the properties of the Free Coinage Gold Mining Co. on Bull hill, near the town of South Altman, is being dismantled and the milling machinery will be shipped to the Morse Bros. Machinery company at Denver. The plant was operated at loss from its inception, and the loss in purchase price, operation, and installation is estimated at fully \$100,000.

The Hondo Gold Mining & Milling Co., C. W. Savery, of Denver, president, has abandoned its lease and option on the properties of the Keystone G. M. Co. on Bull hill, and has removed the mine plant.

The production of the Cripple Creek district for July totalled 87,147 tons with an average value of \$12.84 per ton and a gross bullion value of \$1,119,000.16.

Cripple Creek mining corporations paid dividends in July as follows: Cresson Consolidated, monthly, \$122,000; Golden Cycle M. & R. Co., monthly, \$45,000; Portland G. M. Co., quarterly, \$45,000; Vindicator Con. G. M. Co., quarterly, \$45,000; Granite G. M. Co., bi-monthly, \$15,500. Dividends already have been declared by the Cresson and Golden Cycle companies, payable August 10, at the usual rates.

The work of clearing away the debris of the recent fire at the Last Dollar mine, on Bull hill, commenced July 30. The Catherine Mining Co., Charles Walden, general manager, will build a fire-proof brick and steel structure to house the machinery; an Oregon pine 50-ft. head-frame will be erected. The electric hoist and compressor that went through the fire have been shipped to Denver for repairs. The mine will be in operation inside of three months.

A Denver syndicate, headed by Frank Goudy, has leased the Dante mine, on Bull hill, owned by the Dante G. M. Co., and has commenced work.

The Reid mill, on the Dante property, has been sold to W. C. Hockenbarg, of Aurora, Nevada, and A. E. Chapman, of Denver, and is being dismantled prior to shipment to Mt. Bross, in Park county, Colorado, where it will be used on a gold-silver-lead property.

Carl Johnson, of Denver, owning the Bertha B., situated south of the Cresson mine, on Raven hill, is building an ore-house. He has opened up ore at the 300-ft. level.

W. M. Gilbert has opened up ore of shipping grade on the iron vein of the El Paso-Gold King system, in the lower Gold King adit in Poverty gulch, and is shipping to the Portland mill. He represents an Eastern syndicate.

The properties of the Christmas Gold Mining Co. are to be offered for sale. They are surrounded by the property of the Vindicator Consolidated Gold Mining Co. which owns the controlling interest in the Christmas.

The Cresson company continues to ship high-grade ore and the first of the present week three cars of high-grade ore in bulk were sent under armed guard to the mill of the Golden Cycle company at Colorado Springs. The shoot at the 1400-ft.

level is holding out, and the rich streak has widened to 15 in. of ore, rich in sylvanite, while on both sides of it are 3 to 4 ft. of ore of high grade.

The Captain vein of the Portland system is reported to have passed into the shaft at a depth of 1990 ft., and is of a higher grade than in the level above.

### PORCUPINE, ONTARIO

GRADUAL ADJUSTMENT OF THE WAGE PROBLEM AT THE IMPORTANT MINES.—**DOMES MINES TREATING A LARGE TONNAGE OF LOW-GRADE ORE.**—**NEW MILLS PROPOSED FOR THE DOME AND PORCUPINE V. N. T.**

Among the gold producers of the district, labor is still scarce and restless, owing to competitive bidding on the part of mine managers. The McIntyre-Porcupine, Dome Mines, and Porcupine Crown are paying a rate of wages similar to that being paid by the Cobalt companies, and consequently there is little or no friction. The Hollinger, however, is paying a straight wage of \$4 to all underground workers, which is an innovation in northern Ontario. This is not viewed with general favor in mining circles here. At present it is having the effect of disorganizing to some extent the system of labor classification in vogue at all the other mines of the country.

The Hollinger forces are understood to be satisfied.

With the knowledge that in nearly every instance where deep mining has been carried on in the district, ore of higher value has been found, the Porcupine Crown management has decided to continue the shaft from the 900 to the 1100-ft. level. The 800 and 900-ft. levels have produced the highest grade ore yet taken from this mine. The 140-ton mill is running at a satisfactory rate.

Around 1500 tons of ore daily is being treated at the Dome Mines which is nearly a record in point of tonnage at this mine. The grade, however, is lower as the ore is being drawn largely from the glory-hole and other convenient workings. In some instances the ore runs only \$2 per ton in gold, but being readily accessible to the mill it is being treated at a profit. A new high-grade mill will have to be erected for the economical treatment of the higher grade ores of the lower workings, and it is thought that at the next meeting of the directors it may be decided to discontinue dividends and to convert the surplus, of something like \$700,000, for mill building.

The McIntyre-Porcupine, with a full force, is being developed more rapidly than any mine in the country. Ore-passes have been completed from the 7th, 8th, and 9th levels to the 1000-ft. level allowing transportation of ore along the main-haulage way of that level, thereby reducing costs. At the 1000-ft. level a 4-ft. fan, which is driven by a 15-hp. motor, has been installed. The mill is treating a record tonnage of high-grade ore. The July earnings will constitute a record at the McIntyre.

The installation of additional milling equipment at the Schumacher is proceeding and by the middle of September it is the intention to resume operations provided sufficient labor is available. The mill will then have a capacity of over 300 tons daily.

The Porcupine V. N. T. is developing at the 600-ft. level where the grade and width of the orebody has shown improvement over that in the upper levels. The mill is treating 100 tons per day. About 7000 tons of ore is in the dump, but is being held in reserve. It is the intention of the management to erect a new 400-ton mill as soon as labor conditions will permit.

At the 310-ft. level of the Adanac encouraging results were found. Good ore was found at the 200-ft. level of the Peterson Lake, on the Susquehana lease. The vein for about two rounds maintained a width of three inches, then narrowed to one and a half inches and is lower grade. Temiskaming and

Beaver are still working at the 1600-ft. level with varying results.

In the gold country the labor supply shows improvement. The number of men employed now approximates 2000 as compared with 3000 necessary to run the mines of Porcupine at the maximum. The Hollinger and Dome are the principal sufferers from the labor shortage. Development at the Hollinger is adding to the ore reserves. The new 12-ft. vein at the 425-ft. level of No. 10 shaft is said to be developing satisfactorily. The underground workings are being gradually centralized, which will facilitate the handling of ore following the resumption of operations at full capacity.

The McIntyre-Porcupine with upward of 350 men is treating a higher tonnage and making a higher net profit than ever before in its history. About 530 tons of \$10 ore is being treated daily. With the completion of the additional crushing equipment, the mill will be able to treat 600 tons daily. The Porcupine Crown and Porcupine V. N. T. are treating a large tonnage of ore and are maintaining a good average rate of production. Development is retarded by a shortage of miners.

### COBALT, ONTARIO

UNION MINERS NOT SATISFIED WITH PROMISES AND ARE STILL THREATENING.—**DISCOVERY IN THE LITTLE NIPISSING.**—**THE INCREASING PRICE OF SILVER GREATLY STIMULATING MINING AT COBALT.**—**COSTS CUT INTO PROFITS.**

Despite outward appearances, the feeling of unrest so noticeable among the miner's union during recent weeks has not yet been allayed. For a time it appeared as though the assurance given by the operators would satisfy the mine workers, but the large producers have not posted notices other than those of a few months ago, and the union committee has not withdrawn its demand. Some union men believe that practically they have already won what they desire, and that the bonus now being paid is the result of the attitude of the labor organization. Should the price of silver remain at or above 80c. per oz., thereby automatically entitling the mine workers to another bonus of 25c. per day, which would be 25c. per day more than requested by the union, it would be unreasonable to call a strike. A discovery of a good grade of ore has been made in the Little Nipissing property of the Mining Corporation. The vein is from 1 to 2 ft. wide and is in the southwestern continuation of the Cobalt Lake fault vein. The McKinley-Darragh mine is situated between the Little Nipissing property and Cobalt Lake and will probably be benefited by the favorable developments on Little Nipissing. During June the Nipissing Mining Co. mined ore of an estimated value of \$269,469, and shipped bullion and residue from Nipissing and custom-ores of an estimated net value of \$475,329. The high-grade mill treated 136 tons and shipped 567,409 fine oz. of silver. The low-grade mill treated 6052 tons. The total from this mine for the half year ended June 30 was 1,492,677 ounces.

The increasing price of silver has greatly encouraged and stimulated mining in this district. Only recently bankers in the United States bought 200,000 oz. of silver from the Mining Corporation of Canada, paying 83½c. per ounce, which at the time was an advance of 3½c. over the New York quotation. Recent additions to the Coniagas mill will permit an increase in capacity to treat the sand by flotation, up to 500 tons per day.

With mining costs so great, only the increased quotation for commercial bar-silver has permitted the continued operation of the Cobalt mines in a large way. If the metal were to go below 60c. per oz. under present conditions most of the camp's mines would be obliged to suspend or curtail their work. But in normal times, when labor and supplies can be had at reasonable figures, mining costs are so reduced that Cobalt can mine 45c. silver at a profit.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—P. R. Bradley, of the Treadwell properties, announces that the company has bonded a number of mining claims near Auk bay. The claims will be developed. They were located several years ago by the Dull brothers and two years ago options were given to Aldrich, Valentine, and Sutherland, who have been doing development work ever since. Surface showings indicate that it will make a big mine. The vein is wide and has been traced for several thousand feet.—Over 200 tons of steel from the Treadwell mills was shipped south. Monte Benson, who is in charge of the development being done by the Treadwell company on the recently bonded properties of the Red Diamond, reports good progress. Good reports are coming from Eagle river, where work is being done on a group of claims by M. J. O'Connor, of Douglas, and Dr. Medford, of Treadwell. A 4-ft. seam of coal, 8 ft. below the surface and only 30 ft. from the main line of the Government railroad, has been discovered at Mile 175. The discovery was made by G. Giovannini, who was driving a tap-tunnel to secure rock for a fill. This is the first coal discovery on the line of the railroad. Walter McCray, a Puget Sound diver, has entered into a contract with the Kennecott Mining Co., whereby he is to receive one-half of all the copper ore he retrieves from the bottom of Cordova harbor. During the many years steamships have been loading at that port, it is believed that many tons of copper ore have been lost overboard during loading, and the high price of copper now renders its salvaging profitable.

Mr. Hukelh, appointed by the striking miners at Kennecott to advertise the strike and to urge miners not to go there, has arrived at Juneau and says that the report that the strike has been settled is erroneous; that the miners received a request from Secretary of Labor, W. H. Wilson, to resume work until Government mediators could arrive, promising that they would endeavor to settle the dispute to the satisfaction of all concerned; that the men were ready to return to work, but the company refused to permit the strike leaders to resume work, and the miners then, by secret ballot, voted 209 to 1 against returning to work. Reports from Cordova, on July 21, say the strike situation is improving, and that 65% of the normal force is at work, and the regular output is expected to be reached soon. The Department of Labor has sent a mediator to investigate conditions.

Three new veins of anthracite coal have been opened in the Clark Davis mine at Katalla. It is believed that the railroad from Katalla will be completed by September.

Treadwell, July 22.

(Special Correspondence.)—There is no material change in the strike situation. The men are still out. About 150 men are camped at Blackburn. They still demand a flat wage of \$5.75 per day, but hinting that they will agree to a reduction when copper is below 18c. The company has offered as high as \$6 per day at the present price of copper, but on the bonus system, which was formerly in effect. The saloons are all closed, and consequently order prevails. U. S. soldiers are guarding the mine and important bridges on the railroad.

The Northern Lode Copper Mines Co. property, adjoining the Bonanza mine on the McCarthy creek side of the hill, under the management of W. B. Hancock, is installing an oil-fuel power-plant at McCarthy, 15 miles from the mine, to supply 16,500 volts to drive all the machinery at the mine, and to furnish light for the town of McCarthy. A wagon road is

being constructed for auto-trucks, from McCarthy to the bunkers at Lower Camp, which is connected with the mine by a 6000-ft. aerial tramway. The road is being built up McCarthy creek. There are 180 men employed. The company will commence sinking a shaft when the power is available. Regular shipments will begin as soon as the road is completed. Ore shipments heretofore have been confined to the winter sledding from the mine to the railroad at McCarthy. The ore, chalcocite, is a replacement in limestone near the lime-green-stone contact. During the last winter 2000 tons was shipped. There are two grades, the high-grade averaged 61% copper, and the low-grade, so-called, about 30% copper. This ore also carries an ounce of silver to each 4% of copper.

Cordova, July 14.

During June the Alaska United Gold Mining Co. crushed 20,559 tons of ore in the Ready Bullion mill, producing 608.68 tons of concentrate. The 700-Ft. mill was not operated, but 27.69 tons of concentrate was shipped from there. The total value of the concentrate shipped was \$45,634.66. Operating expense at the Ready Bullion mine was \$43,086.47, representing a loss of \$634.42; and at the 700-Ft. mine the expense was \$9600.20, netting a loss of \$6873.08.

## ARIZONA

The strike situation in south-eastern Arizona may be summarized as follows: A few of the men deported from Bisbee have returned and have been permitted to remain. These men were not miners, but engaged in business at Bisbee, one of them being a restaurant keeper. At Globe it is quiet. The mine operators have arranged to have representatives of the workman's committee meet with representatives of the mine managers twice monthly, for the purpose of discussing and adjusting personal grievances. Special meetings may be called. At Ajo three steam-shovels are operating in the pits, and 4000 tons of ore is going to the mill daily. On July 30, Fred H. Moore, who said he was the personal representative of W. D. Haywood, was escorted from Bisbee to Douglas and there placed on a train and sent to Columbus, New Mexico. The committee at Bisbee stated that they considered his presence in the district a menace.

## COCHISE COUNTY

(Special Correspondence.)—The New Cornelia Copper Co. has acquired the property of the Ajo Consolidated Mining Co., thus adding 24,000,000 tons of ore to its 42,000,000. This acquisition assures a large town at Ajo.

Ajo, July 31.

## GILA COUNTY

Hundreds of miners are daily signing the rolls to return to work in the district, notwithstanding the threats of I. W. W. agitators and others. Those who are willing to work are promised military protection.

## MOHAVE COUNTY

(Special Correspondence.)—J. P. Ryan has been appointed general manager for the Union Metals Co., the operating company of the Fredonia group and the Golconda Annex group of six claims. Some rich ore has been found in the bottom of the Fredonia shaft, 15 in. of which assays \$125 per ton in copper, gold, and silver. Litigation has developed in the transaction whereby the holdings of the Victor Copper Co. in the Jerome district were to be sold to the Jerome-New York Copper Co. for 350,000 shares of capital stock.

Plans are under way to install a large compressor plant in a central location to supply the Banner mine, De La Fontaine mine, and Prince George mine, of the Arizona-Butte company.

It is reported that arrangements have been completed for the installation of a 200-ton dry milling plant on the McCracken Silver-Lead Mining Co.'s property.

Kingman, July 28.

#### PINAL COUNTY

The Magma Copper Co. has reported that its net profits for April were \$195,000, the most prosperous month in its history. This is at the rate of approximately \$10 per share on the outstanding capitalization.

Kelvin, July 31.

#### YAVAPAI COUNTY

(Special Correspondence.)—The Henrietta mine, of the Big Ledge Copper Co., which voluntarily suspended operations in June, due to labor trouble, will soon be re-opened. Because of the closing down of this and other properties the Great Western smelter at Mayer was compelled to close down. This smelter is increasing its capacity 500 tons per day.

Prescott, July 27.

### CALIFORNIA

#### CALAVERAS COUNTY

(Special Correspondence.)—The Keystone mine, situated a quarter of a mile from Railroad Flat, has been sold by E. C. Loftus and J. F. Buck to Eastern capitalists, represented by W. O. Duntley, president of the Pneumatic Tool Co. of Chicago and W. J. Cotton, and it will hereafter be known as the Duntley-Cotton Mines Co. The company is overhauling the stamp-mill and has installed boilers and engines, also a Pneumatic Tool compressor. The shaft is down 270 ft., with levels at 100, 200, and 250 ft. It is reported some good ore has been found. Other prospects are being examined in this district.

Railroad Flat, July 1.

(Special Correspondence.)—W. N. Mahaffey, of Stockton, has been investigating a soapstone and graphite deposit near Campo Seco. It is reported that Japanese capital is interested.

Campo Seco, July 28.

(Special Correspondence.)—The water has nearly all been removed from the Buffalo gravel mine. Sluicing will begin as soon as a dependable supply of water is available. The owners are Wisconsin people.

Mokelumne Hill, July 28.

#### ELDORADO COUNTY

(Special Correspondence.)—Robert G. Hart, representing an Eastern company, and Burr Evans, of Placerville, have been making an investigation of a large gold-bearing porphyry dike 15 miles north-east of Placerville. It is stated that the dike was found to be all that it was represented to be, and that the work of development will follow as a result of the examination.

Placerville, August 4.

#### NEVADA COUNTY

(Special Correspondence.)—At a depth of 800 ft. the cross-cut in the Pittsburg mine, two miles from Nevada City, has cut a vein of sulphide ore that is said to assay \$200 per ton gold, but it will be necessary to make changes in the mill before the ore can be treated to advantage. Cross-cutting continues, to reach the main orebody, where the ore is free-milling.

Sinking is proceeding at the Ocean Star, near Washington, owned by the Columbia Consolidated Co. A vein of good-grade ore is exposed. The company has put in an electric hoist and is adding 10 stamps to the 20-stamp mill. An aerial-tramway is under construction to transport ore from the German and Ocean Star mines to the mill.

The 40-stamp mill of the Allison Ranch Co. has been tested and soon will be running at full capacity. Considerable ore

of milling grade has been opened on the 400-ft. level and preparations are being made for mining in deeper workings. Dewatering of the shaft is making good progress. Most of the miners formerly employed at the Golden Center mine are now at the Allison Ranch. It is stated that the sinking of the Golden Center shaft 1000 ft. deeper soon will be commenced.

Nevada City, July 30.

#### SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. has taken a long-term lease on the Shasta King mine of the Trinity Copper Co. The Shasta King was shut-down eight years ago. The Mammoth is employing 30 men under the superintendency of L. R. Jenkins. The force will be increased. Ore will be shipped to the Mammoth smelter at Kennett. Work is being started at the Central mine, a gold property in Old Diggings. The mine has been shut-down for 10 years. Contracts have been let to sink the shaft in the Silver King mine 120 ft. The mine is five miles west of Redding in the gold belt. The flotation plant at the Afterthought mine, at Ingot, is completed.

A flotation plant of 100 tons daily capacity will be erected at Bully Hill by W. Arnstein, who has an option on the property and has done extensive development at the Star shaft. Fifty-five men are employed. L. C. Monahan is superintendent. It is probable that the force will be increased to 250 men when the flotation-plant is in operation. The Bully Hill mines were shut-down 10 years ago owing to smoke troubles, and the difficulty in smelting ore that contained so much zinc.

Redding, August 1.

(Special Correspondence.)—The Mammoth Copper Co. is building bunkers at Coram to receive ore taken out under lease from the Trinity Copper Co.'s Shasta King mine. Three companies are shipping ore over the Balaklala's tram-line to Coram. The Balaklala ships its ore direct to Coram; the Mountain Copper Co., of Keswick, ships ore from its New Year's claim over the tram-line also. All the copper mines complain of labor shortage, partly due to the Army draft.

Redding, August 3.

#### SIERRA COUNTY

(Special Correspondence.)—The owners of the City of Six quartz mine have let a contract for another 100-ft. of the adit from which a raise will connect with the 40-ft. shaft. Much rich ore was formerly mined in the property. Near the mine a rich gold discovery was made recently by J. Cubit, a prospector.

Gravel mining has been resumed at the Hilo, on Chaparral hill, by the Bernhardt Bros. The workings have been placed in good condition and the water-supply system will be improved. It will be impossible to wash the gravel now being mined before the spring of 1918, because of lack of water.

The Wisconsin Mining Co. has arranged for installation of an electric hoist, compressor, and other equipment at its property in the Forest district. Besides working the gravel deposits, a quartz vein will be prospected. C. Cavagnaro is superintendent.

Additional funds have been provided for the development of the North Fork, adjoining the Wisconsin, and a mill is being talked of. The vein lately found is stated to be developing well. George F. Stone has been re-elected manager.

After prospecting an old gravel channel for five years, the owners of the Mohawk mine on Rock creek have discovered a six-inch vein of ore said to be yielding \$200 per day. John N. Cubit is manager.

Downieville, July 29.

#### SISKIYOU COUNTY

(Special Correspondence.)—The placer season for 1916-17 in the Salmon River district has been above the average. Seven of the nine large placer mines are preparing to close-down for the season, due to the shortage of water. The prin-

cipal mines being operated are the Bonally, Thomain & Teaukert, Bigelow Brothers, Joseph Frazier, John Peterson, Wakes & Mathes, J. Whitfield operating the old Ferguson mine, John Nefrony working the Bennett company's property on a lease, and the Michigan mine. There are many small properties being worked in the gulches tributary to the north fork of the Salmon.

The Bonally mine is worked throughout the year, as water is taken from the river. The other properties are dependent on water from the small streams. These mines extend for 14 miles along the river between Sawyers Bar and the forks of the Salmon.

Florian LeMay of Yreka has some high-grade manganese ore near Red Rock, north of Greenhorn, which he will develop.

It is reported that several diamond-drills are in operation in the Preston Peak district, where prospecting is active.

The Roxbury mines, near Scott bar, have shut-down for the season, due to the failure of water-supply. This company will shortly begin the construction of a 15-mile ditch to take water from Scott river several miles above the mouth of Boulder creek.

David Land, of San Francisco, who has been prospecting the Williams placer on the Klamath river near Wingate creek will resume operation in the district.

Representatives of the Spreckels interest have bought on a tonnage basis the deposits in the soda-beds near Dorris. The deposit is owned by H. E. Weed and C. U. Huff of Dunsmuir, and Fred Tebble of Weed. It is estimated that there is now in the dumps 3750 tons of the mineral.

Hornbrook, July 30.

#### TRINITY COUNTY

(Special Correspondence).—The Estabrook Gold Dredging Co. is putting in a saw-mill to cut lumber for building dredge No. 2, which will be three times the capacity of No. 1. The buckets will hold 18 cu. ft. The hull will be 155 by 50 ft. The company's machine shops, 75 by 155 ft., is the largest building in Trinity county.

The Pacific Gold Dredging Co. is making good progress in tearing down its all-steel dredge at the mouth of Morrison gulch on Coffee creek and moving it four miles down stream to the Graves place on Trinity river. Fifty men and 175 horses are employed. The pit, approximately 200 ft. square and 12 ft. deep, will cost \$10,000. It will be more expensive to rebuild the dredge in its new position than it was to put it up at first.

Trinity Center, August 3.

#### TUOLUMNE COUNTY

(Special Correspondence).—Work has been resumed in the shaft of the Dutch-Sweeney mine. From the 1800-ft. level it will be sunk to 2250 ft. It is reported that a large amount of ore has been blocked out. The machinery at the Yosemite mine has been repaired and sinking resumed. At the Eagle-Shawmut, since the Tonopah-Belmont Co. took the property, the shaft has been sunk 500 ft. and several hundred feet of drifts have been run, exposing a great quantity of ore. Over 100 men are employed, but the number is to be increased. It is reported, but not confirmed, that a cyanide-plant will be installed and the chlorination-plant discontinued. The company has erected a building for the recreation of its employees. It includes a pool-room and a reading-room. Other surface improvements have been made. G. F. Williamson is superintendent.

Molybdenite has been discovered on Knights creek above Columbia by W. P. Jones and E. D. Heagney.

Sonora, August 1.

The Western Exploration Co. of San Francisco has secured an option to purchase mining claims situated in the canyon of the south fork of the Stanislaus near Italian Camp. The option includes the Fortuna mine and Sirius No. 2.

## COLORADO

### LAKE COUNTY

A press dispatch states that the strike of metal miners in the Leadville district, which began July 21, was called off at 12:30 o'clock on the morning of August 2 at a mass-meeting of the striking miners, both union and non-union. The men voted to accept the offer of the operators of a wage increase of approximately 50c. per day.

The Mine Owners Association at Leadville addressed the following letter to Governor Gunter:

"Honorable Julius C. Gunter,

"Governor of the State of Colorado.

"Dear Sir: The undersigned, operators of mines and mining property in the Leadville district, Lake county, Colorado, respectfully submit to your Excellency the following:

"You have appointed the Honorable Platt Rogers and Harvey Riddell, Esq., to investigate and inquire into conditions affecting wages heretofore paid to miners and employees in and about the various mines in the Leadville district, we, therefore, state to you that, although the State Industrial Commission, duly authorized by law for that purpose, has, within the past two months, made such investigation and reported its findings thereon, it is satisfactory to us for the gentlemen designated by you to inquire into the conditions so existing in the Leadville district, and we will afford to these gentlemen every opportunity and assistance for such examination and for learning the conditions affecting the same and any matters which they may deem to be proper subject of inquiry in connection therewith, so as to help them in arriving at a just conclusion whether the wage scale of the Leadville district is fair and proper or otherwise.

"We take this action because we recognize the sincere efforts your Excellency is making to continue the ore production of this district in this time of national stress. We do not believe that any increase of wages is practicable in view of the low grade character of the Leadville ores, but nevertheless we will comply with the findings and conclusions which these gentlemen may, after full investigation, make and report to you.

"It must be understood, however, that no one of us is bound to, or agrees to, mine or operate any property if in his or its judgment mining operation cannot then be advantageously conducted."

The letter was signed by 23 of the more important companies, and as a result it is hoped that some sort of compromise can be effected, and that mining will be resumed. A large number of miners have left the district and others are preparing to leave. Five of the principal mines will probably be closed indefinitely, some of them having pulled the pumps and removed machinery, tools, and cars from underground.

## IDAHO

(Special Correspondence).—Ravenal Macbeth has been selected by the Idaho Mining Association to compile facts and figures on the money invested in mines of the State. Mining is carried on in 27 counties of Idaho, and, in a number of these, large expenditures are being made this year on prospects and in the further exploration of old properties. The largest expenditures, except in Shoshone county, are being made in Idaho county. Shoshone county is the wealth-producing region, but the other counties have mining resources, developed and undeveloped, that are worthy of notice.

Spokane, August 1.

## NEVADA

### ESMERALDA COUNTY

(Special Correspondence).—From its southern workings the Kewanas company has started an east cross-cut to open the main orebody, at a depth of 840 ft. The vein has been developed in Kewanas ground by the Jumbo Junior. A connection between the two mines will be made.

At 320 ft. depth in the Cracker Jack a mass of quartz showing streaks of high-grade copper ore and a little gold is being prospected by a drift.

At the request of Receiver H. B. Clapp, with approval of creditors, Judge Walsh has issued an order for the sale of the milling equipment of the Florence-Goldfield company. This includes the flotation-plant. The company has been receiving an average of \$2000 per month as royalties from lessees, but creditors are demanding a speedy settlement of their claims. It is reported another attempt will be made to reorganize the company and resume work.

The Sunset Mining & Development Co. is preparing to work its Denver group, near Rhyolite. It is said changes will be made in the mill to make a closer saving. San Francisco people are interested.

Goldfield, July 29.

#### EUREKA COUNTY

(Special Correspondence.)—The Croesus Mining Co., under the management of Julius Huebner, has opened a 7-ft. vein of shipping ore on the 400-ft. level and has teams hauling 4 miles to the railroad.

Several mining engineers have been in the Eureka district looking over the different properties with a view to investing, as the large amount of what was formerly considered low-grade ore can now be shipped at a profit.

Eureka, July 28.

#### HUMBOLDT COUNTY

(Special Correspondence.)—The National mine and plant have been taken under lease by the National Leasing Co., which plans to drive a cross-cut from the eighth level of the National to open the extension of the vein, and expects to reach it in four months. Arthur Feust is consulting engineer, and Elmer Pfauts, superintendent.

National, August 2.

(Special Correspondence.)—Near Sulphur, a station on the Western Pacific, 50 miles west of Winnemucca, a deposit of alunite said to contain 10% potash has been bought by Salt Lake City people. It is reported that they were asked to give an option on the property for \$500,000, payable in two years, and one-half the profits. The offer was accompanied by a proposition to build a complete plant to treat the alunite.

Winnemucca, July 30.

#### MINERAL COUNTY

(Special Correspondence.)—Ore shipments from Luning are the heaviest in the history of the district. More than 20 properties are producing with several new shippers to be added to the list. To handle custom ore as well as its own, the Pilot Copper Co., formerly known as the Nevada Champion, will erect a leaching plant. Shipments to the Hazen sampler have been increased by the Wall Street, St. Patrick, Acme Copper Hills, and several other copper companies.

Two large Fairbanks-Morse hoists have been installed at the Luning-Idaho; also a compressor and machine-drills. The Hahn adit, now in 685 ft., is being driven to open at a depth of 200 ft. a large body of ore exposed on the surface of the Sophie claim. Ore assaying 582 oz. silver was recently found there. The Erickson adit has been extended 130 ft. and is being run to reach a large orebody 200 ft. below the bottom of the McDavitt shaft. The management reports a large tonnage of 4 to 7% copper ore blocked out and shipments will soon commence. R. B. Todd, Jr., is superintendent.

The Acme Copper Hills Co. will install a 100-hp. hoist and compressor. Shipments of sulphide ore are going to the Hazen sampler. Several veins from 12 to 20 ft. wide have been cut, and the shaft is to be sunk 100 ft. deeper. The ore is stated to average 5 to 8% copper and 2 to 16 oz. silver per ton. Bernard Eastman is manager.

Following a survey and examination by S. E. Montgomery, of the Nevada Rand mine, at Rand, the company has decided on the early construction of a mill. Sufficient ore is on the

dumps to defray the cost of plant, and a large tonnage of profitable ore has been exposed on the 150, 180, and deeper levels. Driving from the 450-ft. level is advancing to tap the main orebody. The principal veins carry gold and silver in about equal proportions. Charles Huber, of Tonopah, is president, W. V. Rudderow, Reno, secretary-treasurer, and Charles Koegel, of Rand, superintendent.

Sinking of shaft No. 3 is progressing rapidly at the Copper Mountain, operated on lease and option by the Jumbo Extension Co. of Goldfield. The shaft will be sunk to 250 ft. to open the orebodies exposed in No. 1 shaft. Sinking of No. 2 shaft is also proceeding. The ore is in a contact of lime and monzonite, the two main deposits occurring in parallel zones. Shipping has been discontinued pending developments.

It is reported that the second unit of the Thompson smelter will be blown-in within 30 days. The management has obtained additional supplies of coke and sufficient ore has been guaranteed by custom producers to keep a second unit operating. It is also reported the company's Mason Valley Mines is arranging for heavy shipments from its Gray Eagle mine, near Happy Camp, California.

Luning, July 28.

#### NYE COUNTY

(Special Correspondence.)—The No. 3 shaft of the Morning Glory is the only scene of operations at present on this property. A cross-cut from the 50-ft. point in the shaft has been started north to cut the foot-wall of the limestone. Two shifts are employed in this work. The sinking of both No. 1 main working-shaft and No. 3 shaft has ceased, due to a restraining order obtained by the White Caps Mining Co., which claims trespass into its ground by the Morning Glory workings. This means that the matter of extralateral rights will be threshed out between the two companies in the courts, unless a settlement is made out of court.

Manhattan, August 2.

(Special Correspondence.)—The Jim Butler company will begin development from the 900-ft. level of the Desert Queen into the Ophir King property, which was acquired last year. The Ophir King is undeveloped territory lying south of the Rescue Eula. The Ophir King has been recently prospected by a diamond-drill. The extension of the McNamara vein has been tapped between the 700 and 800-ft. levels, showing 4 ft. of ore. The West End vein shows in the face of the west drift of the 8th level, but it contains no ore at that point.

The Tonopah Mining Co. last week milled 2000 tons of ore valued at \$30,000. Development was confined to the Sandgrass and Silver Tops shafts. At the latter a raise has been started to prospect for the extension of the West End-McNamara vein.

The recent development work in the Cash Boy has enabled the company to commence shipping ore valued at \$25 per ton. The ore in sight insures weekly shipments.

The Tonopah Belmont Development Co. shipped 72 bars valued at \$142,058, which represents its bi-weekly clean-up. The east drift on the Shoestring vein, at the 9th level, has increased from 2 to 4 ft. in width, while the value of the ore remains the same.

During June the Tonopah Extension Mining Co. milled 9935 tons of ore of an average value of \$12 per ton, resulting in a net profit of \$42,694.

The West End Consolidated Mining Co. continues to drive the 717D No. 3 toward the east in the hanging wall of the vein, and work has been started in 717D No. 2 on the east side, driving west. In the Ohio shaft cross-cuts 506 and 512 are being driven south under the vein, and the new raises 513, 516, and 517 are all in ore.

The Monarch Pittsburg made a shipment of ore from the 908 south cross-cut, where the vein was reached last week.

The McNamara Mining & Milling Co. is raising to tap the extension of the Ohio vein on the West End company.

Tonopah, August 1.

## MONTANA

## LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Whitlatch mine and mill are in operation at Unionville. Ore is mined from the 400-ft. level. Sherman Bros. have been working the property for several years. The ground west of the 500-ft. shaft has not been explored, but enough has been done to show that a large tonnage is available. The shaft is filled with water below the 400-ft. level.

Extensive development is planned for the Sheep Creek properties controlled by the Illinois Exploration Co. A shaft is being sunk to 1000 ft. Surface development and prospecting has disclosed copper ore in many places. A side-track on the Great Northern railway has been put in at the foot of the hill.

Shipments of ore from the Valley Forge mine, at Rimini, averages one carload per day. The ore is consigned to the New York-Montana Testing & Engineering plant at Helena, where it is concentrated four into one and the concentrate sent to the smelter. The Valley Forge mine has a large tonnage blocked out. Shipments are now made from the ore-dump. The vein is opened to a depth of 600 ft. vertically.

The 300-ft. shaft on the Rock Rose property has been completed and lead-silver ore is being stoped from the 200-ft. level for shipment.

Two carloads are going daily from the Golden Curry group, at Elkhorn. The ore is iron oxide carrying a small amount of gold and copper. The vein, which is upward of 100 ft. wide, is being worked by open-cuts and adit. The Guggenheims have the property under lease and option at approximately \$160,000. Locally the property is known as the Sour Dough group. The ores are consigned to the East Helena smelter.

The Boston & Corbin Co. is mining at Corbin. The ore comes from the 1200-ft. Bertha shaft and is milled at Corbin. The concentrate is shipped to the west-side smelters for reduction. The output of copper is estimated at about 70,000 lb. per month.

A long adit into the Mt. Washington ground, at Wickes, has opened 12 ft. of silver-lead ore at a depth of 800 ft. Shipments are going to the Great Northern at Wickes.

Helena, July 28.

## SILVERBOW COUNTY

Frank Little, an organizer and agitator of the I. W. W., who had made several inflammatory speeches to the miners of Butte, and who referred to the soldiers of the Army as "Uncle Sam's scabs in uniform," was taken from a hotel by a number of masked men at 3:30 a.m., August 1, and hanged to a railroad trestle. Federal troops are camped at Butte and are patrolling the streets.

Hundreds of miners returned to work July 30, says *The Butte Miner*, in the mines of Butte, and aside from this fact there was little of significance in connection with the strike situation, except that a number of electricians, pursuant to the action of the radical element in the union, stopped work. The exact number of electricians who struck was not available, but is believed to be less than 40. The next step in the electricians' controversy will be the revocation of the charter of local No. 65 if it is ascertained that a majority stopped work and that the administration of the union sanctioned the outlaw movement.

## AFRICA

The Ashanti Goldfields Corporation, Limited, has declared dividend No. 35, of 25% (1s. per share) on the issued stock of the corporation, payable August 15.

## KOREA

The Seoul Mining Co., operating the Suan Concession in Whang Hai Province, Chosen, reports the following results for June: Total recovery, \$125,920.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

GERARD LOVELL has gone to New Zealand.

F. H. MITCHELL, of Reno, is in San Francisco.

W. S. NOYES has gone to the Presidio mine, Texas.

KIRBY THOMAS has been examining mines in Ontario.

HERBERT C. ENOS has returned to Denver from New Mexico.

JOHN H. BANKS has returned to New York from Jerome, Arizona.

HERMAN GARLICH, of St. Louis, is in San Francisco on a short holiday.

G. L. SHELDON has returned to Ely, Nevada, from Madison county, Montana.

J. VOLNEY LEWIS is about to go to Alaska and northern British Columbia.

CARL R. DAVIS, manager of the Brakpan mine, Johannesburg, is here on a holiday.

CHARLES B. CRONER is examining properties near Goldfield, Nevada, for Eastern capital.

F. R. WEEKES has been in the vicinity of Tucson for the past month on examination work.

W. H. EMMONS, of the U. S. Geological Survey, was in San Francisco on his way to Mexico.

JOHN A. RICE has opened an office as consulting engineer at 525 Market street, San Francisco.

J. W. BOYLE, of Dawson, has gone to Russia to aid in the reorganization of the railroad system.

C. GORE-LANGTON has gone to Chuquicamata, to serve on the staff of the Chile Copper Co., sailing on August 15.

EDWIN E. CHASE is in the Northern Manitoba, B. C., gold district at Herb Lake and will return to Denver on August 12.

S. W. ECCLES, vice-president of the American Smelting & Refining Co., has been visiting the mining districts of northern Idaho.

B. H. BENNETTS of Tacoma has been appointed consulting engineer for the Ladysmith Smelting Corporation of Ladysmith, B. C.

S. O. HARPER has been appointed project manager of the Grand Valley Project, U. S. Reclamation Service, at Grand Junction, Colorado.

G. B. MARSHALL has resigned as assistant general superintendent of the Abangarez Gold Fields to take charge of Mina la Union, at Miramar, Costa Rica.

M. W. VON BERNEWITZ is in New York, having joined the staff of 'The Mines Handbook and Copper Handbook,' published by WALTER HARVEY WEEP.

ARTHUR C. TERRILL, professor of mining in the University of Kansas, is in the new Kansas-Oklahoma zinc-fields, collecting data for the State Geological Survey of Kansas.

FRANK L. STACK, superintendent of the Mina Carlotta for the Davison Sulphur & Phosphate Co., at Cumanayagua, Cuba, is returning to the United States to offer his services in the Army.

WILLIAM G. DEVEREUX has received a commission as captain in the California regiment of artillery. CHARLES C. DOYLE, of the Mountain Copper Co., is appointed first lieutenant in the same regiment.

W. A. WHITAKER, of the University of Kansas, is arranging for a metallurgical symposium to be held at Boston on September 13, in connection with the fall meeting of the American Chemical Society. Several papers dealing with flotation and metallography will be presented.

# THE METAL MARKET

## METAL PRICES

San Francisco, August 7

Aluminum-dust (100-lb. lots), per lb.	\$1.00
Aluminum-dust (ton lots), per lb.	\$0.95
Antimony, cents per pound	15.50—18.00
Electrolytic copper, cents per pound	31.00
Pig lead, cents per pound	12.25—12.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound	10.50
Tin, cents per pound	80
Zinc-dust, cents per pound	17

## ORE PRICES

San Francisco, August 7

Antimony, 50% metal, per unit	\$1.20
Chrome, 40% and over, f.o.b. cars California, per unit	\$0.70—1.00
Magnetite, crude, per ton	\$8.00—10.00
Tungsten, 60% WO <sub>3</sub> , per unit	26.00
Molybdenite, per unit for MoS <sub>2</sub> contained	\$40.00—45.00
Manganese, 45% (under 35% metal not desired), cents, unit	33—37

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

	Per unit
Above 49% metallic manganese	\$1.00
46 to 49% metallic manganese	0.98
43 to 46% metallic manganese	0.95
40 to 43% metallic manganese	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

## EASTERN METAL MARKET

(By wire from New York)

August 7.—Copper is quiet and nominal at 28c. Lead is dull and steady at 10.87c. Zinc is quiet at 8.75c. Platinum remains unchanged at \$103 for soft metal and \$111 for hard. The average price of tin at New York during July was 62.60c. per pound.

## SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date	Average week ending
Aug. 1	79.00
" 2	80.00
" 3	80.75
" 4	80.75
" 5 Sunday	
" 6	80.75
" 7	81.75

June	22.20	12.85	9.63	Dec.	16.75	11.28	...

The purchase of 23,250,000 lb. of high-grade spelter by the United States Government, originally announced by the 'Boston News Bureau' early in July, has finally been consummated at these prices: 13½c. per lb. for 8,250,000 lb. of grade 'A' and 13c. per lb. for 15,000,000 lb. of grade 'B.' Although the transaction was tentatively closed a month ago, a hitch subsequently arose as to price, much the same as that developing in copper.

The last previous spelter transaction negotiated through the zinc com-

mittee of the Council of National Defense was for 20,286,000 lb., effected in May.

The New Jersey Zinc Co., which up to the outbreak of war had the high-grade spelter field to itself, now finds plenty of competition from American Zinc, Lead & Smelting Co., with its Mascot brand, Anaconda Copper Mining Co., with its Anaconda Electric brand, and other smaller concerns which re-distill a large part of their production in order to get the premium paid over the ordinary grade of spelter.

Recent reports show steady progress in the Nigerian mining industry. The mines of this West African colony are nearly all given over to the production of tin, and, according to the latest statistics, the output of tin ore during 1915 was 6910 tons, as compared with 6144 tons in 1914, or an increase of 766 tons. The output in 1913 was 5331 tons and in 1912 only 2885 tons.

The approximate value of the 20,156,867 lb. of tin exported from Siam in the fiscal year ended March 1916 was valued at \$7,807,703 gold.

The actual percentage of metallic tin in the ore cannot be ascertained, but for revenue-collecting purposes the Siamese government reckons the tin ore which is exported from the east coast of the Malay Peninsula as containing 65%, and that from the west coast 70% metallic tin.

## ORES

Tungsten: There has been little change since last week. Quotations are still \$22 to \$25 per unit for 60% concentrate, with the demand fairly good but supplies none too large. A fair business is reported as put through for foreign and domestic account. Ferro-tungsten is in good demand at \$2.25 to \$2.50 per lb. of contained tungsten.

Molybdenum and Antimony: The molybdenum market continues strong at \$2 to \$2.25 per lb. of MoS<sub>2</sub> in 90% material. There is no trouble in disposing of any ore available. Antimony ore is dull and unchanged at previous quotations.

## Eastern Metal Market

New York, August 1.

The metals are generally dull but steady, and most of them exhibit an upward tendency. The Government price-fixing and purchasing quandary continues retarding the forward swing of business in all metals.

Copper is nominally higher and firmer, but buying is of small volume.

Tin is stronger and steady, but dull.

Lead is higher again, but the demand is at a low ebb.

Zinc has a better tone, is steadier, but is inactive.

Antimony is stagnant and unchanged.

Aluminum is weaker and lower.

Buying of iron and steel products in the past week by the Government has been active. Prices have been stipulated in some cases, but in most instances they have been left until later. This active buying is in contrast with the abstention of private buyers from the market. Present conditions are likely to last for some time, as it is evident that inquiry into steel-making costs will take longer than expected. A more reasonable attitude at Washington on price-fixing is also not improbable. Meanwhile if some of the high prices are lowered, the trade will not suffer. The report of the Steel Corporation for the second quarter of the year shows a net income of \$144,497,000 before taking out fixed charges, etc. This is greater by \$15,000,000 than the total net revenue during the year 1915. The corporation set aside \$87,000,000 for the half-year against expected excess-profit taxes, and \$43,000,000 was reported as expended on new construction since January 1.

### COPPER

The market is a narrow and drifting one with little business reported. Prices are largely nominal, and are not based on large sales, though small ones are reported for various positions. Technically the market has advanced and prices are higher than for the last two weeks. The advance has been caused not by the relations of supply and demand but has been due to sentimental rather than to other reasons. After a period of two weeks of declining prices, the market last week turned upward until the quotation yesterday for both Lake and electrolytic was 29c., New York. This bulge has been due to two causes—the withdrawal of re-sale lots and an idea that large consumers were nearly ready to buy. On the New York Metal Exchange yesterday 50 tons of spot electrolytic copper sold 'under the rule' at 27.75c. cash, New York, against refinery price. There was also a sale of 200 tons of copper rods for delivery, 50 tons each month, July, August, September, and October at 27c. cash, New York, against warehouse receipt. Fourth quarter copper is generally pegged at 27.50 to 28c., New York. Casting copper is reported scarce at 27 to 27.50 cents.

### TIN

The tin market is dull and uninteresting, and the volume of business is not large. It is a halting and ragged market. Early last week there was considerable inquiry for far futures. On July 26 considerable business for these positions, with deliveries into December, was reported, as well as some sales of early shipment from London. On the same day there was a little inquiry for spot Straits, but price-cutting constituted an important factor in this business, sales being made at 62.50c., New York, with quotations as low as 62c. By Friday, July 27, interest on the part of buyers lessened and the buying died down entirely. Previous to this the sales were of a respectable volume. This week, on Monday and yesterday, the market has been uninteresting and slow, with transactions exceedingly light. In fact they were hardly enough to firmly establish

price-levels. On those two days the total sales were about 150 tons. Yesterday future shipment from the East was quoted at 62c., New York. Both Banca tin and Chinese tin are reported scarce. Yesterday the quotation for spot Straits was 63.75c., New York, a progressive advance of over \$1.50 per lb. since last week. The London market has experienced a decided rise in the past week, the quotation yesterday for spot Straits having been £248, an advance of nearly £9. Arrivals up to July 31 have been 2390 tons, with the quantity afloat on that date 3450 tons. The average price for tin for July was 62.60c., New York.

### LEAD

It was intimated in our letter last week that a turn for the better in the lead market was to be anticipated. Events since then have corroborated the prediction. Prices have continued to advance until yesterday the quotation reached 10.87½c., New York, and 10.75c., St. Louis. One cause for this has been the buying up or withdrawal of all outside lots, diminishing the pressure on the market and resulting in a better tone. Business has been done at 10.75c., New York, but this has been the exception. While the leading interest and some of the large producers continue to quote 11c., the market can hardly yet be pegged at that figure. Demand is at a low ebb but outside lots are hard to find. The uncertainties hanging over the market are great and exercise a repressing influence. Another important factor in the situation has been the labor trouble in the West. In four localities these are serious and are limiting the output and shipments. The switchmen's strike at Chicago is delaying the movement of lead. It is no secret that the big producers in Missouri and Colorado are having their operations seriously interfered with by strikes and other labor troubles.

### ZINC

The interesting feature of the week has been the official announcement of the purchase by the Government of 8,250,000 lb. of grade A spelter and 15,000,000 lb. of grade B, but the fact that no decision was made regarding grade C or prime Western was a distinct disappointment. An encouraging fact was the price paid for the two grades referred to. For grade A, 13.50c., St. Louis, was paid, and for grade B, 13c. per lb., an advance of 2c. per lb. over the prices paid for similar though smaller purchases last May. This fact has been accepted as a bullish factor on prime Western when the necessary Government purchases are finally made; nevertheless there has been no immediate effect on the market, which continues inactive and lifeless. Evidences of more interest are accumulating in the shape of inquiries, but actual selling has been of small volume and with better effect in the market. Quotations are largely nominal at 8.50c., St. Louis, or 8.75c., New York, for deliveries as far as October. One sale at this price for delivery up to January has been reported. Any material available at 8.37½c., St. Louis, is believed to have been fully absorbed. The present stagnation is expected to continue until the appearance of large foreign and Government buying. The 'watchful waiting' attitude caused by this uncertainty continues to dominate the general situation.

### ANTIMONY

The market continues dull and inactive with demand at a low ebb. Chinese and Japanese grades are quoted at 15 to 15.50c., New York, duty paid.

### ALUMINUM

It is reported that 100 tons of No. 1 virgin metal, 98 to 99%, was offered at 51c., New York, yesterday. The market is weak and inactive at 50 to 52c., New York, for early delivery.

# INDUSTRIAL PROGRESS

Information furnished by manufacturers

## Knocking Down a 120-Ton Locomotive for Export

Heavy machinery intended for export is often assembled at the factory and shipped on the decks of ocean liners to the distant point where it may be immediately placed in service. Electric locomotives weighing 41 tons each were hoisted to the decks of freighters in New York and shipped completely as-

2400-VOLT LOCOMOTIVE FOR THE BETHLEHEM-CHILE IRON MINES COMPANY

sembled to the Canal Zone where they were used for towing vessels through the locks. There are several other instances where complete locomotives have been loaded directly on the decks of ocean-going steam vessels.

When it was necessary to ship three 120-ton electric loco-

and weight, and box them into shipping-cases of a size easily handled by the ship and dock-cranes. In this form the parts of a single locomotive occupied eight freight-cars and although one package alone weighed 23 tons the shipments were put aboard vessels without mishap and made the forty-day voyage to Cruz Grande.

The locomotives were made and erected in the Erie works of the General Electric Co. just as if they were to be shipped out on their own trucks. Then they were put on test-tracks and given thorough try-outs under actual operating conditions. The tests were made operating under load on 2400-volt direct-current trolley and were of a nature sufficiently severe to bring out any defect of material or workmanship. The regenerative braking-system was given a thorough test with the aid of other 2400-volt locomotives which were being tested for the Butte, Anaconda & Pacific, and the Canadian Northern.

The construction of the Bethlehem-Chile locomotives is along the lines laid down in half-unit of the Chicago, Milwaukee & St. Paul locomotive. There is, however, no arrangement for heating passenger-trains and there are no guiding trucks. The complete unit weighs 120 tons and is equipped with four GE-253, 1500 to 3000-volt motors having a normal one-hour rating of 240 hp. each on 2400 volts. The locomotives are geared for a speed at a rated load of 12.2 m.p.h. and are capable of exerting a tractive effort of 42,000 lb. at the hourly rating. Each locomotive is equipped with Sprague General Electric Type-"M" multiple-unit control and regenerative electric braking-apparatus similar to that used on the Chicago, Milwaukee & St. Paul main-line locomotives.

After the tests were over, and the complete testing data noted, the locomotive was taken apart. The parts were all marked or ticketed in systematic order so that the locomotive could be re-assembled as it stood in test. The knocking-down process started with the removal of the pantograph trolleys followed by taking off the hatch covers of the roof, thus exposing the control and regenerative braking-equipment.

2400-VOLT LOCOMOTIVE LOADED ON CARS FOR SHIPMENT

motives to the Bethlehem-Chile Iron Mines Co. at Tofo, Chile, however, the lifting capacities of the ship and dock-cranes were insufficient for either loading the complete locomotives in New York on board vessels, or for removing them on arrival at their destination. It was therefore necessary to take the locomotives apart, classify the different parts according to size

Through these openings the smaller parts were taken off including the motor-generator set, the air-compressor, and control-equipment supports with contactors.

While these parts were being boxed for shipment, the roof, weighing about 5 tons, was removed. In the building of the locomotive-cab, the roof and sides were assembled with bolts

and nuts, with suitable inside flanges to facilitate disassembling. The usual construction of a cab of this kind would be by the use of solid rivets.

On account of the flexibility of the roof caused by its extreme length (about 45 ft.) this was packed on the platform of the locomotive after the equipment had been unfastened and stripped from it. Following the removal of the roof, all electrical connections were opened up, the various panels, contactor-compartments, and other apparatus were removed and the sides and end framing taken down. The platform proper was the heaviest part of the shipment, weighing about 16½ tons. Together with the roof and the necessary boxing for shipment, this package weighed nearly 23 tons, the heaviest single article in the shipment.

The motors were then removed from the trucks, brake-rigging and other accessory apparatus were also disassembled, the trucks separated, and the axles removed. The larger parts of the shipment for a single locomotive together with weights and dimensions are given below:

	Lb.
Platform and roof (boxed).....	45,800
Truck-frame (unboxed).....	24,000
Motor-generator set (boxed) .....	14,000
Traction motors (boxed, each).....	12,000
Sides of cab (boxed).....	10,000
Wheel and axle (unboxed, each).....	8,000
Air-compressor (boxed) .....	8,000

When completely prepared for rail shipment, the 120-ton locomotive occupied eight cars, including three box-cars for the small package shipment and five flat-cars for the heavier packages and the unboxed parts. Upon reaching the Harlem river, these cars were unloaded onto one of the harbor lighters and transferred to Pier No. 33 in Brooklyn, alongside one of the W. R. Grace & Co.'s South American freighters. The second locomotive was shipped on a typical boat, the S. S. 'Celia,' an all-steel vessel 414 ft. long and 50 ft. beam, having a displacement of 8350 tons with a cubic capacity of 10,000 tons. The speed of this vessel is approximately 10 knots requiring about 40 days for the trip from New York to Cruz Grande. With the exception of the one 23-ton package, the entire shipment was stowed in the hold of the S. S. 'Celia.' This package was lashed to the deck and for this purpose the boxing had been so constructed as to make it weather-proof.

A brief description of the railway upon which these 2400-volt direct-current locomotives will be operated may be of interest since there are several features which are not ordinarily met with in railway operation. This road is 15 miles long extending from the port of Cruz Grande (about 300 miles north of Valparaiso, Chile) to the mining village situated about four miles inland, at Tofo. The iron mine at this point is 2200 ft. above sea-level and consists of two hills of iron ore, which is removed by quarrying.

The railroad is standard-gauge single-track with a uniform grade of 3% for 14 miles, and about one mile near the mines with 1% grade. The trains will consist of an electric locomotive and from twelve to twenty 50-ton ore-cars. On account of the elevation of the line all the loaded cars come down grade. The motive power consists of three 120-ton, 2400-volt, direct-current locomotives operating from a catenary trolley supported on concrete poles on the main line and from a 1200-volt third-rail at the docks. It will be noted that while the mines are only four miles inland the railroad is 15 miles long. This circuitous route was necessary in order to limit the grades and the railroad is constructed in four loops, thus restricting the grade to a maximum of 3%.

A power-plant has been installed capable of furnishing sufficient power for mining and transporting 5000 tons of ore per day with provision for additional equipment to double the capacity. The present equipment consists of two 3500-kw. Curtis steam-turbines generating 3-phase, 60-cycle, alternating

current and one 300-kw., 60-cycle turbine for lighting and small-power service.

The rail sub-station equipment is placed in the powerhouse and consists of two 1000-kw., 2400-volt, direct-current units operating directly from the 2300-volt A.C. busses. On account of the circuitous route, there is considerable saving in feeder copper since a portion of the feeder takes a direct route from the mines to the docks.

In order to provide for suitable control on heavy down-grade work, these locomotives are provided with regenerative braking-equipment similar to that supplied to the Chicago, Milwaukee & St. Paul Railway for use on the main-line electrification. The regenerative braking control will permit the locomotives to descend the grades with ordinary loads without the use of air-brakes, thus returning power to the system and also making appreciable saving in wear on brake-shoes, wheels, and rails.

The air-brake equipment on these locomotives is also of interest since it contains several new features which will enable the locomotive to descend with a greater load than can be held back by the regenerative braking-equipment alone. This outfit provides for either straight or automatic operation on the train alone, the locomotive alone, or on both together. In addition to this the cars are provided with an empty and loaded brake to secure maximum braking-power on each car, whether empty or loaded. The trains will descend at about 12 miles per hour, at which speed with a training-load of 1500 tons, the locomotive will return approximately 1000 kw. to the line. The schedule will be so arranged that the empty train going up will take power from a loaded train coming down the hill.

### Flexible Pipe-Joints

The accompanying illustrations show a new development and what is claimed as being a most decided improvement in flexible pipe-joint construction. The strong feature of these joints is that they have no ground parts and no packing. The port is always of the same diameter, regardless of the flexed position of the joints. When under the highest pres-

SECTION OF A FLEXIBLE PIPE-JOINT

ures they maintain their flexibility, and are absolutely leak-proof. The manufacturers claim to have produced the only joint that will not leak condensed steam. The gasoline and oil-joints are fitted with an all-metal gasket which makes it a 'bone-dry' joint without detracting from the flexibility.

These joints are made in all sizes, from ¼ in. up, and of various types and angles, to accommodate every conceivable

flexibility desired. The double-joint, single-angle will flex to every point of a globe.

For handling compressed air, steam, water, mill-solutions, oils, etc., Flex-O Kant-Leake pipe-joints are finding a wide field in mine, mill, and smelter. The permanence of pipe-lines with Flex-O joints, as compared with armored hose, together with their absolute freedom from leaks makes this equipment particularly well adapted to underground drilling operations and numerous other purposes.

The Flex-O joints are manufactured by the Durbin Co., Pontiac building, St. Louis, Missouri, who will supply details as to construction and operation.

### Headlights and Turbo-Generators for Small Locomotives

The General Electric Co., of Schenectady, New York, has prepared for distribution, bulletin No. 42,014, entitled 'Head-

Diagrams showing the assembly of the turbo-generator set, as well as all necessary data will be found in this 12-page bulletin.

### High-Temperature Burners

E. H. Sargent & Co., of 125 Lake street, Chicago, is the manufacturer of a new form of high-temperature burner for use in laboratories, that is adjustable for both air and gas, and may be successfully used with any inflammable gas except acetylene.

As the chimney of this burner does not move in its adjustment the flame may be controlled without changing the position of the crucible, which is most important in this form of burner. While not intended to supplant the various forms of Bunsen burners now on the market, it will be found desirable when high temperatures are desired, such for instance as the many operations which call for a blast-lamp. Its use is par-

ELECTRIC HEADLIGHT ON STEAM LOCOMOTIVE

lights and Turbo-Generators for Steam Locomotives.' To meet the rigid requirements of locomotive headlight-service, the General Electric Co. has designed a turbo-generator set distinctly novel in its construction and representing the most advanced development in this class of apparatus along practical lines. Three years of exhaustive service-tests and a knowledge accumulated from a vast amount of experience in turbine manufacture have resulted in the building of these turbines with the smallest number of parts consistent with the requirements of good design, durability, efficiency, and close regulation.

The headlight supplied with the turbo-generator consists of an 18-inch silver-plated copper reflector, equipped with a simple focusing-device mounted on a suitable table and enclosed in a steel casing of standard design. The reflector has a 24-inch focal length, which is sufficiently long for accurate focusing of the largest headlight lamps.

In addition to the turbo-generator and headlight, the necessary accessories are furnished in accordance with the requirements of existing headlight practice.

ticularly desirable when platinum vessels are used. Tested on Chicago gas without compressed air, temperatures above 2100°F. have been obtained. The medium and large sizes are best adapted to general laboratory needs. It is made in three sizes:  $\frac{3}{4}$  in., 1 in., and 1  $\frac{1}{2}$  inch.

### National Association of Purchasing Agents

The annual congress of purchasing agents, under the auspices of the National Association, will be held at Pittsburg, October 9, 10, and 11. The programme includes business sessions for the mornings and visitation and inspection of industrial works during the afternoons.

Special features will be: Tour of Pittsburg's principal business districts by automobile during the late afternoon of the first day, and dinner in the evening to be held at one of the country clubs. The banquet will be held at the Convention hotel the evening of the second day, October 10, with speakers of national prominence in attendance.

All purchasing agents, as well as others interested, are wel-

come and expected to attend and participate in the activities of the convention. Special arrangements are planned for the entertainment of the ladies.

### Drilling Contest at Tonopah

An interesting drilling contest was a feature of the Fourth of July celebration at Tonopah, Nevada, at which time some speedy drilling was accomplished by expert drill-runners. The contest was not intended as a competitive test of machines, but rather to interest the miners, and to show what a man could accomplish under ideal conditions. The principal incentive aside from the natural friendly rivalry was the purses of money offered.

There were the usual number of incidents characteristic of drilling contests generally, such as broken drill-bits, careless clamping of the drill-steel in the chucks, and other features annoying to the individual drillers, and which were greeted with sympathy or derision by the interested audience.

Nineteen of the drillers worked with Ingersoll-Rand jack-hammers. Some used Denver rock-drills, others the Sullivan or the Cochise machine.

Following is the official report of the number of inches drilled by each contestant, the kind of machine, and type of bit employed, for which we are indebted to W. H. Blackburn, superintendent for the Tonopah Mining Co. of Nevada.

### Commercial Paragraphs

The firm of WOODS, HUDDART & GUNN, of San Francisco, California, has been dissolved, Charles M. Woods retiring from the firm. The business, however, will be continued by Messrs. Huddart and Gunn at the same place, 444 Market street, retaining the former firm name.

William M. Holman, of the shaft-sinking department of the E. J. LONGYEAR Co., exploring engineers, diamond-drill contractors and manufacturers, of Minneapolis, Minnesota, is a visitor in the Cripple Creek district, in which the E. J. Longyear Co., it is reported, is planning to operate.

The DENVER QUARTZ MILL & CRUSHER Co., of Denver, Colorado, reports the sale of the following equipment to the Onondaga Mines Co., at Palisade, Nevada, the equipment to be used in the remodeling of the mill and increasing its capacity to 100 tons daily: one 8 by 8-in. Denver steel crusher, one No. 2 Denver ore-feeder, one No. 3 Denver quartz-mill, and one Card slimer, together with the auxiliary equipment.

The following new forms have just been issued by the INGERSOLL-RAND Co., 11 Broadway, New York: Form 8006, a 20-page catalogue on Imperial motor-hoists and stationary motors. Form 8212, a 16-page booklet on Little David pneumatic chipping, caking, and scaling hammers. Form 9102, an 8-page bulletin on air-receivers, pressure-tanks, and moisture-traps. These catalogues are profusely illustrated, show tables of sizes and capacities, and will be distributed free on request to nearest branch office of that company.

The receivers of the AETNA EXPLOSIVES Co., INC., announce that they have received orders from the United States Court to continue the company's business in all its branches. In accordance therewith they are vigorously carrying on the manufacture and sale of military explosives to the United States and allied governments and also are devoting particular attention to the domestic business. All of the well established Aetna line of dynamites, gelatins, and blasting supplies will be continued and improved where possible. It will be the policy of the receivers to give the utmost attention to all domestic business, and customers will be assured of dependable and prompt delivery of goods of the highest possible standard of quality. While the receivers say they cannot pledge the policy of the company subsequent to the receivership, it is their opinion that the domestic business of the Aetna Explosives Co. is a sound and substantial enterprise, and they see nothing in the present situation that should operate to affect it harmfully in any way whatever, and they are confident that the production and sale of this company's products for mine, quarry, construction work, and farm will continue indefinitely with increasing success.

### Barreled Sunlight

'Barreled Sunlight' is the trade name given a new paint for interior use made by the U. S. Gutta Percha Paint Co. of 19 Dudley street, Providence, Rhode Island. It reflects the rays of natural and artificial light to distant parts of big work-rooms, increasing the light 19 to 36% by actual test. Its glossy finish can be washed clean, like china, when other paints need re-coating. The firmness of the tile-like surface withstands the jar and vibration of the heaviest machinery without cracking or dusting off. It can be applied over any new or old interior surface by the Rice method specifications.

These are the reasons why it is to be seen in over 4000 great industrial plants. Good lighting in factories, machine-shops, and the interiors of mine-hoist buildings, is as essential as in offices, or elsewhere.

The company will send an interesting book on interior lighting, also a thin board painted with 'Barreled Sunlight.'

Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bdg.; New York, 1760 Woolworth Bdg.; London, 724 Salisbury House, E.C.  
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

# Speed up with Electric Power

*G-E Equipment is reliable and economical*

**H**ERE are some of the ways in which modern industry has been speeded up by putting electric power to work in the right place.

Metal mines have boosted output to meet world-wide demands. Great central power plants in place of small local plants in coal mining areas now supply cheaper electric power per ton output for each mine. All tonnage records have been smashed in the steel industry. Greater automobile output has lowered prices and given better road transportation. More and better cloth has been produced at lower power costs.

The engineering problems solved in putting electric power to work in these and other industries were many and intricate. Production of electrical equipment suited to this work and in quantities required is an important part of this company's service to American industries.

Any problem involving the use of power can be simplified by the application of electricity. The General Electric Company is well equipped to lend valuable assistance in working out such problems and is glad to co-operate with manufacturers and engineers in every possible way.

# EDITORIAL

T. A. RICKARD, Editor

WE shall be glad if mining engineers and metallurgists will notify us when they enlist or obtain commissions in the Army or Navy. No news is more interesting at this time.

COPPER production is being curtailed at the rate of about 50,000,000 pounds per month, a quantity equal to the annual output of one big mine. The Miami and Inspiration mines, both idle, produce 17,000,000 pounds per month.

A REVIEW of a book on another page of this issue will give keen pleasure to many of our readers, not only because it is interesting, but because it is signed by James F. Kemp and signifies that he has almost recovered from his recent illness. In behalf of Professor Kemp's many friends in the West we send hearty greetings.

BURMA'S big mine, the Bawdwin, belonging to the Burma Corporation, continues to gain in resources. The latest annual report shows a reserve of 3,644,000 tons of ore, averaging 25.2 ounces silver per ton, with 27.4% lead, 20.9% zinc, and 0.5% copper. During the first half of the current year a production of 10,387 tons of lead containing 924,000 ounces of silver has been made.

OROVILLE Dredging Company is the name of a corporation that not only exploits dredging ground at Oroville but engages in a similar kind of mining in South America. It is one of those British companies to understand which it is necessary to know something about geography. The work at Oroville is done by a subsidiary company, which reports having paid four dividends each of 12½ cents during the last fiscal year, digging 3,164,136 cubic yards averaging 7.65 cents per yard at a cost of 3.90 cents per yard. The company, through another subsidiary, also operates dredges in the Pato district, in Colombia. During 1916 the yardage excavated was 1,484,721, averaging 48.5 cents per cubic yard at a cost of 12.46 cents per cubic yard. The contrast in yield and cost is eloquent of the difference in local and technical conditions. On the Nechi, an adjoining property operated by a third subsidiary, the yardage during the year was 1,617,975, averaging 49.27 reducing his cost as much as he had expected, but he has cents, at a cost of 9 cents per cubic yard, and of this cost 5 cents is debited to repairs on the dredges. The rise in the price of materials and the increase in freight-rates have prevented Mr. W. A. Prichard, the manager, from

done well and is to be congratulated on developing a highly productive dredging-area.

SOME idea of the expansive effect of the War on American commerce is afforded by the statistics of foreign trade. These show that during the first half of the current year the exports were worth \$3,289,517,427, as against \$1,232,942,074 in the corresponding period four years ago. The excess of exports over imports in the first six months of 1917 was \$1,735,736,710, as against \$326,437,957 in the first half of 1913. Another comparison is furnished by the U. S. Steel Corporation, whose net earnings were \$267,619,094 in the first half of 1917 as against \$38,451,381 in the half-year immediately preceding the War. Part of these gains is due to higher prices, but most of it is caused by the increased volume of business.

DEFINITIONS, if correct, serve to clarify ideas. We are glad therefore to note the definition of 'ore' given by Mr. Charles H. Fulton in Technical Paper No. 143 of the U. S. Bureau of Mines. Professor Fulton's definition is as follows: "An ore is a metalliferous mineral, or an aggregate of metalliferous minerals, more or less mixed with gangue, containing metal of commercial importance in such quantity that it may be extracted at a profit by the application of economic and skilful methods of mining and treatment." He explains that "this definition restricts the term 'ore' to natural mineral products yielding a metal, and makes only such material 'ore' from which the metal may be extracted at a profit." We commend this definition—it seems long—and length is a defect because every additional word introduces a chance for mental derailment—but it is both clear and comprehensive. Most of our readers may prefer it to the definition suggested by the present writer, namely: "Ore is metal-bearing rock that can be exploited to economic advantage."

IT is amusing to see how the *Boston News Bureau* lays stress on the high cost of producing copper and insists piously that "the real cost means the elimination of miscellaneous credits, such as 'other income' derived from sale of precious metals recovered in the ore treated, dividends from holdings in other companies, be they mining or affiliated railroads, and interest on bonds or loans." Not only these items but depletion of assets, depreciation of plant, and taxes are to be included in the 'cost.' How different from the irresponsible statements concerning 6 and 7-cent costs appearing in the same

paper in the less serious boom period of an earlier day. Now the *News Bureau* states with unction that an important copper-mining company "has discovered that its 'real cost' approximates 17 cents a pound." Again we are told: "The net result is that copper costs in the United States today are nearer 20 cents a pound than 10 cents, heretofore regarded as a normal average." Even this is not enough; under the shadow of the tax-collector the *Bureau* says: "It will be found that the cost of producing copper will range from 15 to 25 cents a pound in the case of the large companies and even higher among some of the smaller ones." It is lucky that this estimation of cost stopped at this point; the editor of the *Bureau* might have wiped out the whole copper industry in his belated enthusiasm for severe statistical truth.

**I** NTEREST continues to centre in the potash market to such an extent that we publish the current quotations elsewhere in this issue. The Government has been dilatory in legislation for the disposal of potash-lands either by locating or by leasing. In Washington we detect no sense of the necessity for haste in any matter touching our preparation to meet the exigencies of war. All known domestic sources of potash were withdrawn from location until the manner of throwing them open to the public should be determined by congressional action. A bill providing for leasing potash deposits had reached a point where agreement between the House and the Senate was in sight, and it was then delayed by an amendment limiting its application to Searles Lake in California. Meanwhile measures are being taken to produce potash as a by-product in Wyoming, and the output from cement-works and from the dust in furnace-gas at iron smelters is growing in importance. Interest in the use of raw sulphur as a fertilizer is widening, and this method of utilizing that element, when done with an understanding of the physics, chemistry, and microbiology of soils, is remarkable for the amount of potash that it liberates in the form of assimilable potassium sulphate ready to serve as plant-food.

**A**T the time we wrote the editorial 'Why We Fight,' in our last issue, we had not seen the articles by Mr. Gerard appearing in the Hearst papers. Despite the disreputable medium of publicity used by the former ambassador to Germany and despite the blatant manner of their publication, it is evident that they will serve an excellent purpose in enlightening the public, particularly that part of it which has had no better source of information than the Hearst papers. Even now, ignoring the anti-German character of the Ambassador's disclosures, the *Examiner* prints a letter of flatteringly praise for one of its miserable editorials, quoting a correspondent who says: "Yesterday I saw a lot of fine and nice young fellows in soldiers' clothes on the streets, and I tell you it is a crying shame to let them go to death, for a matter that don't concern us in the least, and they are thinking that they will have a 'picnic'." If this cor-

respondent knows so little concerning the purpose for which these young men are being sent to battle, it is because the editor of the *Examiner* has been misleading him by what he chooses to call, in the headings to two congratulatory epistles, 'Editorials that Struck Home' and 'Splendid Editorial.' The lack of a sense of humor is pitiful; but the publication of such disloyal stuff is worse.

**M**EXICO is in need of cash, the military expenditure alone for 1917-1918 exceeding the total expenses of Madero's government in 1912-1913. So Señor Carranza is casting sheep's eyes at Washington and is beginning to talk pro-Ally instead of pro-German. It is highly probable that the Mexican government will announce itself as anti-German and propose becoming an active ally of the United States in order to obtain a loan, and to import munitions of war. Meanwhile the oil-wells and mines in Mexico are being taxed heavily in order to get some sort of revenue from a country devastated by brigandage. If the United States grants a loan, is it too much to expect that one condition for granting it will be the assurance of protection to American interests in Mexico?

## Let Us Help Mr. Hoover

At last the food bill has been passed by Congress and Mr. Hoover has been appointed by the President to administer this new department of national service. The passage of this useful and necessary legislation has been so delayed as to have lost the opportunity for conserving the harvest. For this regrettable delay the country may blame Senator Reed, whose malicious and persistent attack on Mr. Hoover is yet without any sort of explanation. Let us forget it and concentrate our attention on the purpose to which Mr. Hoover has dedicated himself in a spirit of public service that makes us proud to claim him as a member of our profession. To the readers of this paper, all of whom know Mr. Hoover as an engineer of extraordinary intelligence and executive ability, it will be a matter of professional, as well as patriotic, pride to further his efforts to prevent wastage of food, so that not only we in this country but the peoples of our Allies may be adequately nourished during the times of stress incident to this world war. The day for talk has passed, each and every one of us must co-operate in the national effort. Let us 'get behind Hoover' at once. Therefore we ask our readers to sign this pledge:

### I promise

1. To have at least one wheatless meal per day.
2. To eat beef, mutton, or pork not more than once per day.
3. To reduce the consumption of butter at table and in the kitchen.
4. To use less sugar in tea, coffee, and cooking.
5. To eat local products such as vegetables, fruit, and fish, so as to save the food necessary for our soldiers and allies.

6. To urge economy of food at home, and outside, especially at clubs and hotels.

Let each man sign this pledge. We signed one like it several weeks ago. In order to further the good cause we print this pledge on page 43 of our advertising supplement. Please sign it, cut it out, and send it to this office. It will be our pleasure to collect the pledges and forward them direct to Mr. Hoover as one of many proofs that the men of the metal-mining industry are supporting him whole-heartedly. Do it now!

## Misuse of Terms

We have been impressed lately—as often before—by the confusion of thought produced by the incorrect application of technical terms, for example, the misleading phraseology of most of the flotation patents, in which it is stated that such and such a proportion of oil is to be used “per ton of ore.” The weight of the ‘ore’ has nothing to do with the weight of oil required in froth-flotation. The function of the oil is to aid in separating the valuable mineral from the valueless gangue; the underlying idea is that the oil will ignore the bulk of the ‘ore’, namely, the gangue, and apply itself usefully to the small portion of the particular mineral it is intended to concentrate. Therefore it is foolish to talk of 1% of oil “on the ore” when the ore may contain as much as 25% or as little as 1.5% of the concentratable mineral, requiring ten or twenty times more oil in the one case than in the other. Another persistent blunder is the custom of speaking of the cost of milling, in California, for example, as, say, 35 cents per ton, when this does not include the cost of extracting the gold out of the pyritic concentrate recovered after amalgamation or alongside cyanidation. The cost of treating this concentrate is \$9 to \$17 per ton, equivalent to something like 30 or 35 cents per ton of mill-feed. Therefore the cost of ‘milling’ is nearly double the figure commonly quoted. This inaccuracy of statement arises largely from a failure to distinguish between ‘recovery’ and ‘extraction’. A metal is ‘extracted’ when it is in marketable form; it is ‘recovered’ when it has been collected or concentrated in a form assuring successful extraction. Thus a flotation-plant ‘recovers’ copper in a concentrate that is sent to a smelter, where the copper is ‘extracted’. The Spaniard and the educated Mexican distinguish between *recoger* and *extraer*. We read description of mills or other metallurgical plants in which we are told that some metal has been ‘extracted’ at a given cost; this would indicate a handsome margin of profit, if indeed the metal had been ‘extracted’, but the series of metallurgic operations has not been completed and considerably more cost must be incurred before the metal ‘recovered’ in an intermediate product is finally ‘extracted’ and ready for sale. The transactions of technical societies will show such blunders as the use of ‘slacked’ lime. ‘Slacked’ has no meaning; ‘slaked’, the correct spelling, is full of meaning. When one pours water on lime it reminds one of the Sudan thirst described by G. W. Stevens; the lime

sizzles and gurgitates as if in ecstasy of absorption. The ‘slaking’ of lime is a pictorial phrase; the ‘slacking’ of it describes nothing. Others, equally careless, speak of a concentrating table for treating slime in a mill as a ‘slimer’, which means a maker of slime. The termination ‘-er’ signifies agency. The proper term is ‘slime-table’. Sometimes it is a ‘de-slimer’ table, if it happen that the object is to discard the valueless gangue-slime in order to concentrate the valuable pulverized mineral. The ‘mat’ of froth or the ‘mat’ of timber in the caving systems of mining is often spelled ‘matte’ incorrectly, suggesting something entirely different. ‘Classify’ and ‘size’ are used almost interchangeably. In milling, to ‘classify’ is to group particles of equal mass; to ‘size’ is to group particles of equal dimensions. One more: ‘Chute’ and ‘raise’ are employed confusedly. The opening or chimney made through rock is the ‘raise’, whereas the slide or inclined trough at the outlet is the ‘chute’. All raises are not provided with ‘chutes’ nor need a chute lead from a ‘raise’. The distinction is particularly important when describing the shrinkage and caving systems of mining. Such distinctions are always important, because they indicate care on the part of the writer, they favor a habit of mind that conduces to clear expression, they are the mark of the technician as against the blundering of a mere scribbler. The man that writes carelessly and expresses himself in a slovenly manner is not to be trusted with scientific research.

## Flotation Litigation

Litigation over the Minerals Separation patents has reached an interesting stage. It will be useful to review the present status. On December 11, 1916, the Supreme Court of the United States reversed the decision of the Ninth Circuit Court of Appeals in the Hyde case, and found that patent No. 835,120 was valid. On May 21, 1917, the Third Circuit Court of Appeals decided that the Miami Copper Company had infringed that patent and also No. 962,678, this latter covering the use of a soluble frothing-agent. No petition for a re-hearing was filed by the Miami company. Ordinarily the mandate of the Appellate Court would have been sent down to the District Court at the expiration of 30 days, this mandate being the official notification to the lower court of the decision of the upper court, but the mandate has been stayed for a period of two months, so that the Miami company is allowed three months, or until August 21, for filing a petition in the Supreme Court praying for a writ of certiorari whereby the case can be carried to that court for final review. Evidently, therefore, it is the intention of the Miami company to make an effort to bring the case before the Supreme Court. If that court should refuse to grant the writ of certiorari, the next step ordinarily would be for the case to go back to the lower court and be referred to a Master in Chancery for the purpose of making an accounting. For the purpose of the audit, witnesses would be examined before

the Master by each of the parties to the case and from their testimony the Master would decide the sum to which Minerals Separation is entitled as royalty upon the Miami operation and in the way of damages suffered by Minerals Separation.

Meanwhile the Supreme Court's decision in the Hyde case did not avail Minerals Separation against the real infringer, in that case the Butte & Superior company. After Minerals Separation people won the first round in the Hyde case before the District Court at Butte they brought suit against the Butte & Superior company and moved for a preliminary injunction. This was in the autumn of 1913. The Butte & Superior case was heard before the local court that had first tried the Hyde case and it, in the person of Judge Bourquin, ruled that no injunction would be issued if the Butte & Superior company filed a bond and also filed monthly reports of its flotation operations with the Clerk of the Court. This was done in due course. No injunction was issued and the case rested until, as a sequel to the Supreme Court's decision in the Hyde case, it was brought to trial on April 16, 1917. Whatever the decision, it is likely to be followed by an appeal, which would be heard before the Ninth Circuit Court in San Francisco, the court that gave the one decision wholly adverse to Minerals Separation, namely, the decision in the Hyde case against which they appealed successfully to the Supreme Court. Whether the Butte & Superior case will reach the court of last resort remains to be seen. The Supreme Court may refuse to grant a writ of certiorari, in which event the Butte & Superior case will not be reviewed by it. A reasonable expectation exists, having regard to the importance of the issue and the new evidence, particularly with reference to the so-called critical point in the addition of oil, that the Supreme Court will be willing to hear an appeal in the Butte & Superior case when the time comes. In that event Minerals Separation will have to explain why they have repudiated the need of an increased or different agitation, and have thrown aside their contention for the existence of a 'critical point' in the use of oil, both of these factors in controversy having been urged in the Hyde case as essential features of patent 835,120. In the Hyde case Minerals Separation persuaded the Supreme Court that the process of their patent is characterized by a different and increased agitation and by adherence to a critical quantity of oil. By reason of these contentions, denied point-blank in the Butte & Superior case, they won the most important decision given so far. Will not the Supreme Court treat any further claims of Minerals Separation with grave suspicion? The latter might say that they were mistaken in the theory presented in the Hyde case, and that subsequently they had found that no critical point exists and that the agitation of the prior art is sufficient. They might then claim that the patent is valid notwithstanding and that until the discovery set forth in patent No. 835,120 had been made nobody knew that froth-flotation could be performed with an amount of oil so small as to make the process economically prac-

ticable; that they discovered the method of conducting the process with this small amount of oil; and that thereby they took the process from the category of scientific curiosities into the class of industrial arts. Thus they might claim that the patent was valid even without the critical proportion of oil and the critical kind of agitation. The answer to such a contention, cynically regardless of all their previous testimony in the courts, would be a declaration that there was no patentable discovery in ascertaining the least amount of oil that could be used, this being merely the result of such economy as is incident to the commercial development of any metallurgical operation.

It would seem to the onlooker that if this litigation had arrived at the Supreme Court with the evidence now available, it would have proved unfavorable to the patentees. The fact is, of course, that, when Messrs. Sulman, Picard, and Ballot applied for their patent, they did not know how nor why they obtained their froth; even when the validity of the patent was first tried, eight years after it was issued, neither they nor their opponents understood the rationale of the process, and during the four years that have elapsed the various claims and assertions made in the course of litigation have been stultified by new data both from the laboratory and the mill. Not having penetrated the underlying principles of flotation, it is no wonder that their patent failed to cover the essentials of the process; nor does it seem just that they should, by an accidental decrease in the proportion of oil—a proportion now known to be non-essential—be enabled to make a blanket claim for a monopoly of a process that has proved, thanks largely to the work of others, to be of so great an importance to the mining industry. We have seen oil added to pulp in the so-called critical proportion and fail to perform any function as a flotation-agent, and we have then seen a pulp so treated suddenly develop flotative phenomena by the addition of a soluble resinous material, while another portion of the same pulp yielded its mineral more abundantly to the froth by adding oil in larger quantity. The question will be asked, has the Supreme Court been known to reverse itself? Yes, several times. We refer, for example, to a question of mining law, at issue first in *Lavagnino v. Uhlig* (198 U. S. 443) and then in *Farrell v. Lockhart* (210 U. S. 142). The decision in the second case squarely reversed the decision in the first. No man can prophesy the judgment of a court of law in a patent suit, but we, prejudiced by viewing the case from the standpoint of the welfare of the mining industry, repeat our forecast, made more than a year ago, that before this litigation is ended the use of oil will be abandoned. Shall we then have some fresh hocus-pocus to explain the real inwardness of a soluble frothing-agent? Perhaps. But that too is based on a quicksand of ignorance concerning the fundamental physics. Meanwhile the litigation is costing each side about \$250,000 per annum. Is it to be a war of attrition? We hope not, for a principle is at stake, and it is well therefore that the litigation should go to a final decision.

# DISCUSSION

*Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.*

## Physics of Flotation

The Editor:

Sir—The many notable papers that have been published in the MINING AND SCIENTIFIC PRESS have shown that there has been rapid progress recently in applying the principles of physics to the explanation of the problems of flotation. The word 'flotation' brings to mind immediately the celebrated principle of Archimedes, that is, the principle of buoyancy, on which depends the determination of specific gravity and the sorting of bodies in water according to their relative mass. Thus we see that it is excessively easy to separate crushed quartz from sawdust, no matter how thoroughly they may be combined, merely by throwing the mixture into tranquil water, when, necessarily, the quartz will go to the bottom and the sawdust will rise to the surface. Considering that ores are a mixture of minerals which at times possess great differences in the specific gravity of their constituents, it would occur to one to form a fluid medium in which to float some of these, like sawdust, while others would submerge, as in the example cited above. Without casting thought as to the question of undertaking to prepare such a liquid practically for separation, it may be worth while to point out that since, in the usual order of things, we are accustomed to see that solid bodies determine the form and the movement of liquid bodies, the metallurgist confronts precisely the inverse relation of the solid and liquid bodies in the problem of flotation, the liquid being employed in greater mass than the solid to cause it to move, the solid previously having been reduced to exceedingly small dimensions. Thus differences in the behavior of the solid have been introduced, whereby the simple principle of Archimedes is affected by the phenomenon of capillarity. On account of the relation between the solid and liquid being distinct from that which we are accustomed to consider, and principally because of the great variety of combinations which may be formed through the changes in the several factors of which each one in the problem is susceptible, such as density, volume, and superficial area of the particle, and, on the side of the liquid, its density, fluidity or viscosity, and its ability to mix with gases or other substances to modify its action, it is probable that the professor of physics will not be able promptly to reduce the metallurgic principles of flotation to a law or to a simple formula for application in the industry. It is interesting to note, however, that in some respects the holding of the finely subdivided mineral particles in the interface between two films is analogous to the phenomenon which we call capillarity, as observed in a

liquid in relation to a solid large in size as compared to the quantity of the liquid involved. While the explanation deals with energy-relations between the films, nevertheless, it may be interesting to think of the phenomenon from this standpoint.

BENJAMIN REZAS.

Denver, Colorado, July 26.

## What is a Metalliferous Mineral?

The Editor:

Sir—The prevalent acceptance of terms is that generally applied in legal definitions, at least in the framing of laws. Only in the interpretation of patents and in the construction of contracts should a court undertake to penetrate the deeper significations and distinctions of science. The basis of judicial interpretation, according to the logic that the lawyers have drilled into us for generations, is the intent of the parties drawing up the agreement. In one sense legislation also partakes of the nature of contract; it is an agreement made between the representatives of the electors on behalf of the commonwealth and of the individuals of which the commonwealth is composed. The ideas held by these competent contractors on behalf of a self-governing people is what the court necessarily must endeavor to ascertain in order correctly to dispense justice. It certainly would not have occurred to the senators and congressmen that framed our land laws to undertake to distinguish between metals, non-metals, and metalloids. As a matter of fact, it would be difficult to obtain corresponding classifications by different chemists relative to such elements as hydrogen, tellurium, tin, arsenic, antimony, bismuth, vanadium, tantalum, and tungsten. These are capable of being reduced to an elemental and solid state, in which they possess the appearance of metals, but their relations in the making of chemical compounds display a divergence from the characteristics of such metallic substances as copper, silver, and lead. What does this divergence in character mean? Would you class a bat with the birds because it has wings and learned the art of aviation before that other mammal, Orville Wright, astonished the birds at Kitty Hawk, North Carolina, in 1903, by daring to invade their realm? Although the Land Office officials are not members of the judiciary, they do exercise judicial functions, and are supposed to be bound by the same rules of evidence. What evidence would the Land Office invoke to exclude vanadium from rank as a metallic element that would pass before a committee of the American Chemical Society? The same official has undoubtedly handled metallic antimony, and has been

impressed with the fact that it possesses some appearances that might lead him to confound it with lead. Would he also exclude antimony? I fear that his distinctions are the outgrowth of unfamiliarity with vanadium. Many mining claims have been located according to the mining law upon antimony deposits in the West. Are these, then, illegal?

COURTENAY DE KALB.

Palo Alto, California, July 20.

## The Nitrate Fizzle

The Editor:

Sir—It is, I think, unnecessary to state that I hold no brief for Secretary of War Baker nor for those working under him, when I say that I think your editorial entitled 'The Nitrate Fizzle' was a little too sweeping. Admittedly we are at war, and there should be no shilly-shallying in the assurance of a supply of so all-important a substance as nitric acid, still, does that warrant our following the charted courses of other nations when we are not navigating in their waters? While the direct combination of the nitrogen and oxygen in our atmosphere by the aid of the electric arc should theoretically result in the conversion of 42% of the gases entering the furnace into nitrous oxide, in actual practice the gases issuing from the furnace rarely contain more than 2.5% of that substance. Up to date, then, in the matter of fixing atmospheric nitrogen we seem to have 'little on' the Azotobacter, Clostridium, or the rest of the group of nitrogen-fixing organisms.

The indirect methods, of which you gave a survey, seem to offer greater possibilities. They are not nearly so wasteful of power, and are therefore not dependent on huge, cheap water-powers—or on water-power at all—for their success. If in the United States there is developed water-power to be obtained cheaply enough to make the direct fixation of nitrogen a success I am not aware of it. To develop latent water-powers of the proportions required for the process takes time. Dams have to be built, pipe-lines laid, and transmission-wires erected to a suitable shipping-point. On the other hand, many coals suitable for the manufacture of producer-gas are to be had at favorable shipping-points. United States coals are not, as a rule, high in nitrogen content, nevertheless, in converting them into producer-gas I think they may be relied on to give 70 lb. of ammonium sulphate and upward per ton of coal. This, at the present price of sulphate, which is \$6.50 per 100 lb., is worth \$4.55 and higher. A steam-plant fired by producer-gas can be built infinitely more quickly and cheaply than a water-power plant of the same energy, and, as the sulphate obtained should considerably more than pay for coal, sulphuric acid, and cost of making sulphate, it starts with an advantage over the water-power plant. Then, too, in war time, with representation of the enemy in our midst that is by no means negligible, is it not wiser to have our eggs in a number of baskets rather than all in one? None of us knows, of course, exactly what those in control are doing, but it seems likely that

the aim will be the making of nitric acid in a number of plants by one of the indirect methods through ammonia, and if a little of the latter substance can be obtained by the way from coal, so much the better. I, for one, do not look for useless experimenting from those in charge. There is little doubt that improvements can be made on some of the indirect methods, and I believe plants will be so constructed that, if experiments fail, nitric acid will still be able to be produced in them by proved methods.

F. H. MASON.

San Diego, Cal., August 10.

[We fail to see any essential difference in opinion between Mr. Mason and ourselves, but we are glad to bring the facts once more into the open. The reasons why we applied the word 'fizzle' to the Government administration of the trust created by the passage of the nitrate law are exceedingly simple. The bill was passed a year ago; its enactment was in large part a response to petitions and communications from constituencies that regarded it is a necessary safeguard in the event of war; the sum of \$20,000,000 was appropriated, and this sum, large as it is, was generally recognized as barely sufficient for a plant on a scale that might be considered commercial, and actually inadequate to supply our needs if the Chilean source of sodium nitrate were to be cut off; a commission was appointed to select a site for the plant, and this body treated its duties as if they were no more than the settlement of an economic question in piping times of peace, and the report was delayed to a point that exasperated the patriots of the country who were eager that every measure for 'preparedness' should be hastened. Finally the department responsible for action announced its intent to use but one-fifth of the sum appropriated and to apply that in the erection of several experimental plants, and no steps were to be taken to utilize the remaining \$16,000,000. The result is that \$4,000,000 will be expended within the coming year, and that no plant of commercial importance will be built; we will remain dependent chiefly on Chile as before. Nothing has been done to promote our independence of a foreign supply of fixed nitrogen, and, as the fund is being administered, nothing will be accomplished that will give us such independence within the next twelve-month. If that is not a 'fizzle,' what synonym should be used to describe it? If a commission appointed by the Imperial German Government had been in charge of the matter the outcome could hardly have been more satisfactory to Kaiser Wilhelm. Private concerns have offered their plants for research and production of fixed nitrogen, among these being the American Cyanamide Co. and the Nichols Chemical Co. The latter placed its Laurel Hill works at the service of the Committee on National Defense for developing a process claimed to be superior in point of cheapness. This, however, is apart from the issue: Congress appropriated money for a plant to supplement private enterprise for national protection, and the intent of the bill has not been carried into effect.—EDITOR.]

# Control of Emulsions in Flotation

By COURTENAY DE KALB

Flotation engineers have found that fine grinding of ore facilitates concentration by oils when the proper 'frother' and 'collector' have been pre-determined experimentally. On the other hand, a complaint is generally lodged against what is called 'primary slime,' derived from ore containing abundant decomposed hydrated derivatives from silicates. The presence of foreign matter, such as iron filings and undecomposed original granular constituents in the ore, will often overcome the disadvantage caused by the slime. It was, therefore, not an inherent property in the slime itself that produced the trouble; it was the absence of material that could develop favorable interfacial energy-relations that constituted the obstacle to flotation. Perhaps it might have been overcome in other ways. The use of certain salts, especially some haloid salts and hydratable sulphates, often will dispose of the slime difficulty, though for a different reason. This indicates that in these cases a condition leading to de-hydration favors the delivery of oil in flotation in such manner that it may function properly in oiling bubble-films and mineral particles.

It is important to think of the oil as being 'delivered' to the film and to the mineral particle in an effective way. The oil is not present as a miscible substance in the pulp that receives treatment in the flotation-cell; it is there as an immiscible substance, and to be effective it must first be dispersed through the pulp. A merely miscible substance, so far as we know, will not produce the effect that is observed in a foam carrying mineral to the surface of water. In order to do its work the oil must be dispersed; but that is not all; it must be locked up in a medium that will prevent the re-coalescence of the dispersed particles until wanted, and then delivered at the proper speed and in the proper amount as needed. The oil in such a system is the dispersed body, and the substance in which it is dispersed is the dispersion-medium; the two together constitute what is known as the 'dispersoid.' This is expressed in terms taken from colloid chemistry, and they apply exactly. An oil dispersed in a suitable medium is, however, a coarse dispersion compared with the more nearly molecular dimensions of the particles composing a true colloidal dispersion; therefore the old term 'emulsion' is useful to distinguish it from colloidal dispersions. The difference, nevertheless, is one of degree only. Furthermore, the difference between a persistent emulsion and one that breaks the moment the energy maintaining the dispersion is withdrawn is probably as great as that between the size of particle in a persistent emulsion and of a body brought to a colloidal degree of dispersion.

Before proceeding to a closer examination of the

characteristics of emulsions it should be observed that emulsification is a result of the expenditure of energy; it represents work done in overcoming the forces of attraction which bind the molecules of the oil into masses of greater than microscopic dimensions. The practice of making emulsions commercially has shown that the application of force, in a manner similar to what is known in ore-crushing as abrasion, most readily and perfectly tears the particles of oil into lesser particles, reducing them to emulsifiable dimensions with an expenditure of power less than that required to accomplish the same result by beating the oil into the dispersion-medium. That is merely because the power, in this method of application, is concentrated more perfectly upon the work of rending the particles of oil instead of being expended largely in the useless effort of stirring a mass of material in which the rending of the oil-particles is incidental to the churning of the mixture. It will be apparent at once why the rotary mechanical agitators that have to do the work of emulsifying the oil while they also keep the pulp in suspension consume a large amount of power as compared with the effect obtained by grinding the oil with the pulp through a tube-mill and subsequently forming the foam for floating the mineral by the expansion of highly dispersed compressed air in the flotation-cell. The term 'foam' is used advisedly, because it is more accurately descriptive than 'froth,' and serves to link it, as must be done for properly understanding it, with the colloidal dispersions of which it is merely a good example of the gas-in-air type. In the Callow cell a true 'foam' is produced, although on arrival at the surface the freer expansion against the atmosphere develops a coarser mass of bubbles, which quite appropriately is called a 'froth.' There is a distinction, with a difference, between the foam produced in the body of the relatively dense pulp, and the froth with its disturbed energy-relations where the bubbles are exposed on the surface of the pulp to the light gaseous medium of the atmosphere.

Having seen that oil may be dispersed most readily in its dispersion-medium by the rending action produced between two surfaces impinging upon it and moving in opposite and parallel directions, that is, by abrasion, the nature of an emulsion may be considered. The making of emulsions and their properties have been subjected to careful investigation recently by Martin H. Fischer.<sup>1</sup> He defines an emulsion, in its simplest form, as a di-

<sup>1</sup>'Fats and Fatty Degeneration: A Physico-Chemical Study of Emulsions, and the Normal and Abnormal Distribution of Fat in Protoplasm.' Martin H. Fischer and M. O. Hooker. John Wiley & Sons, 1917.

phasic system consisting of a mixture of two immiscible liquids. Two types of emulsions are recognized, dependent upon the relative quantities of the two substances, that is to say, with much water and little oil the result would be a dispersion of oil in water, known as an oil-in-water emulsion, and, on the other hand, a water-in-oil emulsion would follow the dispersion of a given amount of water in a preponderant volume of oil. It has been claimed by some practitioners of flotation that a small amount of oil beaten into the water of the pulp makes a water-in-oil emulsion, which would signify a continuous oil-phase and a discontinuous water-phase. It is not conceivable that the oil could exist as an elastic tenuous medium under a strain that would stretch it to a point approaching its elastic limit, and hold it as a dispersion-medium involving the dispersed water-phase. If it were true that such a dispersoid could be obtained in a flotation-cell, then a contradiction to previous experience would have been found, proving that the laws of dispersed bodies, as hitherto ascertained, were in error. The dividing film, the interface, between two liquids dispersed the one in the other, is more than a wall of division; it is a surface within which energy-phenomena develop; where condensation of molecules occurs, producing what is known as 'adsorption'; where orientation of the molecules is observed in each of the surfaces of the two liquids in opposition; and where interfacial tensions are set up. These are phenomena in direct contra-distinction to the increase in tenuity of a stretched elastic medium, especially in respect of the condensation of molecules that imparts to the oil-film, for example, a density increased approximately to equality with water wherever water and oil come into contact. Molecular condensation is contraction of volume, and it is at the extreme from extension. Again, if a perfect emulsion of a mineral-oil, that is, of a stabilized emulsion of the oil-in-water type, capable of infinite dilution without breaking, be brought into contact with a mineral particle, the particle does not become oiled, but, if a water-in-oil emulsion be used, the oil, in what is then the dispersion-medium, is available, and does actually oil the surface of the particle. On the other hand, a temporary emulsion of oil in water, which endures only while energy is being applied to the dispersoid by means of agitation, will also yield oil to cover the surface of a mineral particle. Further investigation would determine the proportions at which a simple emulsion of the oil-in-water type may or may not deliver the oil out of the dispersoid to form films upon solid bodies or to enter as a third phase into the water-air interface when bubbles are made. Dr. Fischer states that no spontaneous emulsion ever forms when oil and water are brought into contact; also that no persistent emulsion of the oil-in-water type can be produced in which the oil exceeds a fraction of 1%. Data as to the breaking of such an emulsion are wanting. Lewkowitsch<sup>2</sup> affirms that oils and fats will not emulsify in water at all, no matter how intimate the

contact. Actually, as will appear on further consideration of the composition of an ordinary mill-pulp, no such simple emulsion as the oil-in-water type would be obtainable in any case, because in such a mixture conditions exist for the making of an entirely different character of emulsion. The possibility of a water-in-oil type, in the proportions used in practical flotation, is wholly contrary to experience in the formation of emulsions. It must be remembered that an oil is a neutral glyceride of a fatty acid that is not miscible with water; it is also insoluble. Mineral oil is also immiscible and insoluble. Certain so-called oils consist of mixtures of compounds, some of which are soluble, and others hydratable on reaction with some alkaline or aluminous substances. These, in part, are colloidal bodies that perform an entirely different function from oils. They may even constitute a phase facilitating the dispersion of the oil, thus serving as an assistant in emulsification. Such substances belong to the class known as hydrated colloids.

Two kinds of colloids are recognized, namely, suspensions and emulsoids. The prime characteristics of bodies in the colloidal state are that they do not diffuse nor dialyze, and that they display the Brownian movement. The colloidal realm, of which these two features are distinctive, is a higher state of dispersion than an emulsion, but lower than a molecular dispersion. Molecular dispersions readily dialyze. Typical molecules have diameters ranging from 0.1  $\mu$  to 1  $\mu$ , that is, from a ten-millionth to one-millionth of a millimetre. A molecule of starch, however, has a diameter of about 5  $\mu$ ; it is accordingly a large molecule; furthermore, it shows colloidal properties, hence it may be considered an approximate measure of the minimum colloid dimension. A substance capable of molecular dispersion in water is one that is soluble, using the word in its more popular sense; it will diffuse through a thin parchment of collodion membrane. If a test-tube be coated with collodion, as soon as the solvent has evaporated, a thin skin will be left, like a glove on a finger, that may be slipped off. If this collodion sack be filled with a solution of a salt, and the sack then be stood in a beaker of distilled water, so that the level of the water without and of the solution within coincide, the salt will gradually pass through the pores, although they are too small to be visible with the most powerful microscope, and in a short time the same quantity of the salt will be found in any unit volume of the liquid either inside or outside of the sack. This process of diffusing through such a membrane is known as dialysis. It is characteristic of molecular dispersions only. A substance with particles greater in size will not dialyze; therefore colloids, though the particles dispersed are on the limit of and beyond microscopic visibility, will not diffuse through such membranes, and they may be accurately discriminated from the molecular dispersions in this manner. The movements of molecules are persistent and extremely complicated. Colloids, though relatively large, do nevertheless approach near enough to the molecular dimensions to partake of this tendency to ceaseless mobility; the

<sup>2</sup>'Chemical Technology of Oils, Fats, and Waxes.' 1915. Vol. 3, p. 108.

result is a zig-zag motion of the suspended particles, particularly observed in those that do not become hydrated. This dancing of the particles, like an irregular and non-rhythmic gyration, is called the Brownian movement in honor of its discoverer, Robert Brown, an English botanist, who first noted it in 1828. It is a special characteristic of the non-hydratable colloids that constitute the class known as suspensoids. As soon as a colloid takes up water it becomes enlarged and the solution in which it is dispersed becomes more homogeneous because of this adsorption of the dispersion-medium, hence the Brownian movement ceases. Another distinction deserves mention. When substances are so dispersed as to lie within the colloid realm the solution becomes optically heterogeneous, and when a narrow pencil of light from an arc-light passes into a vessel having parallel sides, and containing the colloid dispersion in distilled water, an intense greenish-white luminous cone flashes into view. This is the famous Tyndall cone. It is characteristic of that class of colloids known as 'suspensoids.' The other class, called 'emulsoids,' fails to display this peculiar optical phenomenon because of this property of adsorbing water, which in a manner is analogous to salts that undergo hydration. Therefore, by such 'hydration,' or, more specifically, by such 'solvation,' having taken up a large quantity of the dispersion-medium, they fail to exhibit sufficient difference of refraction to produce the Tyndall cone; that is, the dispersoid containing a solvated colloid is optically more nearly homogeneous.

The significant point to the flotation metallurgist is that an emulsoid is composed to a large extent of the dispersion medium, firmly held until released by a change of state induced by a third substance that possesses the power of dehydration. Neutral salts will dehydrate many solvated colloids, thereby increasing their dispersion even to the point of diffusibility. Sulphates, citrates, phosphates, alcohol, sugar, and many other substances, cause dehydration of emulsoids, while cyanides, iodides, and chlorides increase the adsorption of water; the chlorides, however, show several maxima and minima in their effect, following the varying degrees of concentration of the salt in the solution. Most pronounced in their action in promoting hydration of the solvated colloids are acids and alkalis. Almost any hydratable colloid will swell through the adsorption of water under the influence of an acid or of an alkali. On the other hand, a colloid thus hydrated through the assistance of an acid will become dehydrated upon the introduction of an alkali, and the reverse.

Colloids of this class, because they display a desire for water, are called 'hydrophilic,' or water-loving colloids, while the suspensoids that refuse to take up water are called 'hydrophobic,' or water-hating colloids. Common hydrophilic colloids are soaps, gelatin, albumin, casein, and silicic acid. The last is produced in mill-pulp as a result of attrition on the ore. The longer and the more finely the ore is ground the larger will be the quantity of this hydrophilic gel-colloid present in the solution. A series of such gels is formed from the grinding of dif-

ferent silicates, and the quantity formed increases with great rapidity by prolongation of the time of grinding. If the ore be either distinctly acid or distinctly alkaline the hydration of these colloids, and their consequent swelling, is immensely increased.

Reverting to the teachings of empirical methods, it is interesting to take an old pharmaceutical description of emulsions: "Emulsions are those preparations in which oleaginous substances are suspended in water by means of gum, sugar, carrageen, yolk of egg, etc. In general it will be found that the bulk of the emulsifier must first be taken, while the oil should be added little by little, rubbing them together in a mortar, and taking care that the oil is completely absorbed or emulsified before further additions. Should too much be added, the effect is to throw out most of the oil already incorporated; it is then almost impossible to remedy the error." It should be added that soap is also commonly used as an emulsifier, as well as acacia, blood-albumin, dextrin, and other substances. All the substances mentioned are hydrophilic colloids. The peculiar and outstanding phenomenon, as pointed out by Dr. Fischer, is that a perfect emulsion is obtained only when all the water, that is, the whole of the dispersion-medium, has been absorbed by the hydrophilic colloid. A perfect emulsion, so made, possesses a high degree of persistence. It will last without breaking for days, and months, even for years. The quantity of oil that can be emulsified in this manner with certain substances, such as casein, is enormous. For example,<sup>3</sup> two grammes of casein, 0.8 cc. sodium carbonate (in molar dilution), and 21.2 cc. water, produce a mass that will swell enormously and acquire aropy consistence. Into this may be incorporated gradually by mixing, with abrasion, any desired quantity of oil up to 150 cc. or more. Such an emulsion will be stiffer than a well-made mayonnaise, and will endure for an indefinite period in that condition. I have made such emulsions with ordinary flotation-oils, even using the light 'stove-oil,' and no tendency to break after prolonged keeping has been observed when the dispersion of the oil into the hydrophilic colloid had been sufficiently thorough. Want of laboratory facilities has prevented me from making similar experiments with silicic acid and other hydrophilic colloids, which result from the wet-grinding of ores. Investigations with such substances offer a field for study that promises to throw much light upon the phenomena of flotation; they may lead to more accurate control of the conditions desired for obtaining a still larger measure of economic success.

The breaking of an emulsion will take place under many conditions, depending upon the character of the hydrophilic colloid used. Soap is capable of so high a degree of dispersion as to be practically soluble. Accordingly mere dilution of an oil-in-soap emulsion will release the oil and permit of the re-coalescence of the droplets. The soap of commerce also lowers the surface-tensions of water to an extreme degree; and this is true of soaps accidentally made in flotation by combination of

<sup>3</sup>Fischer, *loc. cit.*, p. 36.

alkaline or aluminous bases in the mill-pulp with the fatty acids, resin, or phenol, in some oil-mixtures employed. Other emulsions, such as those with casein, may be diluted to any degree without breaking. They make, in effect, a milk, in which the minute oil-droplets of the emulsion are surrounded by protecting films of the swollen colloid. I have made such emulsions with common flotation-oils and have diluted them in the proportion of 1 of emulsion to 1000 of water. No separation of oil occurred, even after standing for weeks, but the emulsion rose to the surface of the water after the manner of a cream. An emulsion of this kind, in which an alkali has been used as a hydration-assistant, will instantly break upon adding sulphuric acid to a point beyond neutrality. A salt having the power of de-hydrating the colloid will also break the emulsion, the water then separating from it in free form, while the oil rises to the top. An emulsion made with a carbo-hydrate, such as acacia, dextrin, or starch, however, is not broken by the addition of acids, alkalies, or the ordinary dehydrating salts. The mere presence of such a hydrocarbon stabilizer in either oil-in-soap or oil-in-protein (casein, etc.) emulsions tends to restrain the breaking by acids, alkalies, or salts. In this connection it is pertinent to quote the following highly significant statement from Fischer.<sup>4</sup> "Following the general laws governing the distribution of a third material between two phases, an emulsion will frequently stand heavy dilution with water, or the addition of materials which dehydrate the stabilizing colloid, without breaking, if the colloid material either is from the first, or comes to be, concentrated<sup>5</sup> in the surface between the oil globules, and the aqueous phase. This is why oil-in-protein emulsions resist the addition of water, and will not break easily even when powerful dehydrating agents are added to them. It also explains why the addition of suspension colloids (suspensoids) or their production (as in the case of the finely divided metals) in an oil-water mixture gives the emulsion a fair stability. Through such adsorption-effects and the protecting films thereby drawn over the oil globules, these may be kept from coalescing even though every other opportunity is offered them to do so. It is only for this reason that dilution alone does not suffice to break every emulsion."

The best results in emulsification are obtained with substances that take up the most water and form fairly viscid liquids with any amount of water added to them. The viscosity of a solution containing a suspensoid, even in considerable concentration, is not greatly increased above that of the pure dispersion-medium, but emulsoids increase the viscosity with extreme rapidity as the concentration of the emulsoid in the solution becomes

higher. Gelatin shows progressive augmentation of the viscosity up to the point of forming a solid jelly, when the amount in solution reaches 2%.<sup>6</sup> Changes in temperature, however, are of great importance, the viscosity of water decreasing 2% for every degree of rise from 0°C. to 25°C., and the decrease in viscosity of gelatin is enormously more rapid. Associated with the changes in viscosity, due to varying proportions of hydrophilic colloids added to solutions, is the phenomenon that they present of serving as a protective covering to the dispersed droplets of oil to form an emulsion. Therefore it can be comprehended why some particular degree of concentration can be found for any emulsifier in which it will most perfectly perform its function, and, referring to our old pharmaceutical recipe, we observe that the empirical maker of emulsions had discovered that the progressive dispersion of the oil was the one sure way of obtaining a stable product. This principle is not applied as yet by the flotation operator. He either incorporates the oil all at once or too rapidly, and usually under conditions admitting of no more than an exceedingly coarse dispersion. It is evident then that a large part of the oil used is unable to fulfil its purpose, except as the proper conditions are experimentally discovered in the case of each ore. The wet pulverization of ore for flotation reduces a considerable quantity of the gangue and mineral to particles so comminuted as to lie within the colloidal realm; the mineral particles that are triturated to a degree rendering them colloidal belong almost entirely to the class of suspensoids, while the gangue, for the most part, on coming within the colloid realm of dispersion, is found to belong to the class of emulsoids. Some of these are excessively hydrophilic and serve excellently for the emulsification of oil, and in such cases it is seen that there is less need of 'frothers'; others are not so hydrophilic, and assistants to the emulsification are then required. Incidentally, since suspensoids possess the faculty of stabilizing the oil-film on a bubble, while hydrophilic colloids do not possess this property, one more reason for the preference between gangue and mineral in flotation is apparent, at least as related to the highly comminuted particles. The swelling of hydrophilic colloids, moreover, does not progress rapidly in a neutral solution, but it takes place readily in a solution that is distinctly either acid or alkaline, which reveals a reason for the use of one or the other of these assistants, and it also shows that with a neutral ore it would usually not matter whether acid or alkali were added to promote the colloid solvation; but if the ore should react faintly acid then more acid will usually improve its emulsifiable quality, whereas a faintly alkaline pulp would indicate the need of more alkali. It is important, however, to discriminate between the alkaline substances present. An ore with superabundant soda or potash, or aluminates of soda or potash, will respond favorably, while an ore that liberates lime on

<sup>4</sup>Loc. cit., p. 53.

<sup>5</sup>Obeys the law of colloid concentration toward a discrete phase, whether solid, liquid, or gaseous, or, as re-stated by Wolfgang Ostwald as a generalization of Willard Gibbs's theorem, "adsorption will take place whenever there exists in a surface a difference in energy-potential, which can be decreased through a change in the concentration of the dispersed materials bordering upon this surface."

<sup>6</sup>Wolfgang Ostwald: advance proofs of a forthcoming volume, 'An Introduction to Theoretical and Applied Colloid Chemistry,' to be published in September by John Wiley & Sons.

grinding will be expected to prove stubborn in yielding its mineral to flotation. Calcium oxide requires little water for hydration; when present under conditions that yield soaps the calcium base is so strong as to make a calcium soap at the expense of the weaker alkaline bases, and this at once breaks the emulsion. A calcium soap may be used as an emulsifying agent, but will not stand dilution. The presence of lime, therefore, may prove a serious deterrent, although sometimes advantage may be taken of its properties as an emulsion-breaker to deliver oil out of an emulsion, when such an emulsion is added to a pulp, at the rate needed for supplying films to bubbles and to mineral particles. This function of lime has not been overlooked in flotation, though no systematic use of it appears to have been made; it has been applied in certain cases empirically. Colloid chemistry gives the explanation and establishes the principle for its use. In the same way the hygroscopic quality of a salt determines its function in breaking a non-diluted or a non-dilutable emulsion. A soap-emulsoid can be used as an emulsifier to make an excellent emulsion, but it cannot be diluted beyond a relatively low point without thereby breaking the emulsion; lime, or lime chloride, or a hygroscopic sulphate, will also break it without dilution. It is conceivable that some ores may produce hydrophilic colloids, which yield soap on the addition of fatty acids, resin, or phenol, and that the maximum concentration of these colloids for good emulsification may be reached. This could happen only in a practically lime-free pulp, and in such a case lime could be used as an emulsion-breaker. It must be noted that silicic acid, like soaps, is an emulsoid possessed of but little elasticity, and on dilution it behaves similarly to them. How far the presence of organic compounds in some mill-waters may serve to stabilize emulsions made with the assistance of the solvation-colloids in the pulp is an inviting subject for investigation. The function of the 'frother' is to form, with the dilute alkalies present, substances that hydrolyze and behave in a manner analogous to soaps. This occurs with compounds yielding resin and phenol. Resin, in fact, is employed to some extent as a substitute for fatty acids in the manufacture of soap. These are particularly efficacious in the emulsification of mineral-oils, although the protein emulsoids possess this power in a higher degree.

A consideration of the foregoing leads to the belief that a more perfect control of the conditions for delivering flotation-oils to the mineral in the pulp and to the foam produced in a pneumatic cell, could be accomplished by making an emulsion with the aid of a hydrophilic colloid, using either acid or alkali as an assistant, according to the character of the pulp to be treated, diluting this emulsion for convenience in adding it in proper proportion to the pulp as the pulp enters the cell, and establishing the proper conditions of acidity or alkalinity in the pulp to cause the breaking of the emulsion so as to deliver its oil at the rate needed for the flotation of the mineral. In my experiments I have done this, and have found that the oil was liberated in such manner as

to oil the bubbles and attract and lift the mineral successfully, the froth being normal, and buoying its burden of mineral in orthodox fashion. This method admits of exact regulation of the oil, and of applying it effectively to do the work demanded by the quantity of mineral to be floated. The power required for the making of such an emulsion in suitable amount is extremely small compared with that needed for the types of mixers now in use, and the result is more nearly perfect. My experiments also indicate that if advantage is to be taken of the emulsoids produced by grinding the ore or those originally present in it, the nature and the quantity of these substances in any given case must be ascertained, in order that the necessary assistants to solvation may be added, and that the correct degree of dilution may not be exceeded, otherwise a good emulsion will not be formed. The organic hydrophilic colloids that could be used will rarely require as much as a half-ounce per pound of oil finally emulsified, and their cost will range from two-tenths to half of a cent per pound of oil so used, even at present exaggerated prices.

DUST from cement kiln gases consists of a mixture of raw material from the 'mix,' ash from fuel-combustion, and volatilized alkalies. There is considerable potash in the dust, both in a soluble and an insoluble form, the soluble portion being potassium sulphate produced by combination of the potash in the 'mix' with the oxidized sulphur derived from the fuel; if there is a deficiency of sulphur the potash forms a carbonate. The slowly soluble potash is probably in the form of silicate resulting from combination of incandescent particles of potassium oxide with the silica from the ash. This becomes soluble by treatment for several hours with hot water, the presence of lime hastening the solution. Slowly soluble potash compounds are also formed by the interaction of potash salts in solution with silicious material, this recombination being greatly accelerated by heat. It is partly because the potash in cement kiln dust is not all given up at once on contact with water but is slowly dissolved, that it possesses peculiar value as a fertilizer. A high-grade potash-bearing dust contains about 20%  $K_2O$ , or 30% of the sulphate ( $K_2SO_4$ ), and about 1.5% locked up as silicate. Cement mills now prepared for saving the potash-bearing dust are taking pains to add to the mix suitable high-potash aluminous material in order to increase the output of this valuable by-product. The average dust from cement kilns contains about 10 to 11% total  $K_2O$ , of which about 86% is readily soluble in water.—R. J. Nestell and E. Aderson in *Jour. Ind. Eng. Chem.*, July, 1917.

SILICATES containing alumina, on being ground in the presence of water, produce colloidal material of indefinite composition co-existing with a liquid containing dispersed alumina and silica.

NITRATE OF SODA is selling at New York at \$4.25 per 100 lb. on the basis of material 95% pure.

# An Electric Furnace

By A. W. FAHRENWALD

In the course of experimental work in determining the freezing and dripping points of certain slags, I developed a furnace suitable for high temperatures. I have described it elsewhere.\* In principle this furnace is similar to all furnaces where the heat is obtained by the resistance offered to the passage of an electric current by a suitable resistor. In the furnace described, the resistor is a helix of Acheson graphite made thus by sawing around a tube of graphite of suitable inside and outside diameter, then spacing the saw-marks according to the size of furnace desired.

This is a convenient and inexpensive furnace when not larger than 6 to 8 inches high and 2 to 3 in. diameter (crucible area), but when the helical resistor is applied to turbo-furnaces of probably a couple of feet in length, the construction of them is somewhat difficult. For this reason I have devised a resistor made from Acheson graphite which is extremely simple and is suitable for tube-furnaces of any desired length.

Fig. 1 shows a longitudinal section of the furnace.

\*Chemical & Metallurgical Engineering, May 15, 1917.

Fig. 2 shows a cross-section on the line *AB* of Fig. 1. Fig. 3 illustrates the principle of the heating unit if unrolled from around the inner alundum tube.

Referring to Fig. 2 and 3, the current, for example, passes down *d* up *c*, down *b* and up *a*, and so on through the entire series of Acheson graphite rods, thus forming the resisting unit, which in this case is about 26 ft. long by  $\frac{1}{4}$  in. diameter.

In making a furnace of this kind, the proper diameter and length of resistor can be found by laying out parallel to each other, on a table covered with asbestos, a certain number of graphite rods and connecting alternate ends together with copper wire and passing an electric current through the series. In this manner the proper number can be obtained beforehand. If a certain number of rods is desirable the resistance can be regulated by varying the diameter of the rods. Rods of any diameter can be obtained from the Acheson Graphite Co. at Niagara Falls.

The furnace shown requires about 30 amp. at 110 volts. I am not prepared to state how long this furnace will

FIG. 1. LONGITUDINAL SECTION OF FURNACE

last; this, of course, depends upon the temperature of operation. The helical furnace described in the reference above cited gave excellent service, and this should do better on account of the perfect insulation of the bars, which are surrounded with alundum cement and the whole inclosed between two alundum tubes. When the bars give way they are readily and cheaply replaced

fastening two bars together are made from discs of graphite 1 in. thick and  $2\frac{1}{2}$  in. diam. with a hole in the centre equal to the outside diameter of the inner alundum tube. These, one at a time, are fastened firmly to a similar wooden model with holes properly spaced. Through these holes, which receive the ends of the graphite rods, holes are properly distributed in the graphite disc. These are then placed over the inner alundum tube and the graphite rods, which are cemented firmly in place with alundum cement. The discs are then sawed between every other bar on the top one and likewise on the bottom one, the first cut on the bottom disc being one bar farther around than the top disc, thus giving a continuous circuit, for the passage of an electric current. The material sawed out is also replaced with alundum cement.

This furnace should be convenient for experimental heat-treatment of steels as well as for other purposes. I am also of the opinion that its use could be extended to the treatment of cyanide precipitate, by increasing the diameter of the crucible, also the number and diameter of the resistor-bars. Those who have inquired regarding making a tube-furnace from the helical resistor will find this type more convenient and easier in construction.

A SAD COMMENT upon the inability of the American people to learn the savage lessons of war is contained in a recent official statement from the War Department. Despite the persistent pleading of well-informed officers of the Army no steps have been taken in the years of menace to provide equipment for the manufacture of modern heavy artillery. In consequence we find ourselves now absolutely incapable of producing the guns that we will need, and the United States has been compelled to place orders with the already overburdened gun-factories of France in a desperate effort to meet the emergency. A number of 75-mm. guns and 150-mm. howitzers have been contracted for abroad, and it is suggested that it may prove a speedier solution of a part of the difficulty to enlarge some of the French

works to accommodate our demand for artillery to use on European battlefields than immediately to attempt to provide such equipment at home.

MANGANESE deposits are being developed in the Republic of Panama, and at several points on the Pacific slope in Costa Rica and Guatemala.

FIG. 2. CROSS-SECTION OF FURNACE ALONG A-B

FIG. 3. RESISTOR-BARS

with new ones. The particular advantage of this construction over the helical one is the uniformity of cross-section of the resistor-bars, thus giving a uniform heat throughout the system.

In the construction of the furnace, the required number of bars is firmly bound in a bundle and sawed the required length. The end pieces, A, in Fig. 2 and 3,

## Use and Testing of Oxygen Mine-Rescue Apparatus

\*The value of oxygen mine-rescue apparatus is becoming more appreciated both for rescue and recovery purposes. There has been a steady growth in the establishment of rescue stations throughout the country, particularly in the Western coalfields. In training miners the Bureau of Mines teaches the use of three types of apparatus—the Draeger, the Fleuss, and the Westfalia. The bureau itself is developing a fourth type, known as the Gibbs. Each of these has a steel cylinder containing oxygen at a pressure of approximately 2000 lb. per

an apparatus-party of only two men made an exploration of considerable length, and one of them lost his life. Until such practices are discontinued the dangers incident to wearing apparatus in irrespirable atmospheres will not be reduced to a minimum. Some men while wearing the apparatus fail to appreciate the fact that the added weight of the apparatus causes exhaustion more quickly than when working without it.

During the fiscal year 1916 tests were made with the four types of mine-rescue apparatus mentioned to deter-

LUNG MOTOR AND PROTO EQUIPMENT. TWO VIEWS

square inch and a reducing valve that allows a definite quantity of oxygen per minute, at a pressure slightly above atmospheric, to pass from the cylinder to a reservoir from which it is breathed by the wearer. The air exhaled by the wearer flows through to a compartment containing regenerating material, usually caustic soda (sodium hydroxide), by which the carbon dioxide in the breath is removed. The regenerated air joins the stream of oxygen from the reducing valve and is breathed again. The possibilities and limitations of such apparatus are becoming more thoroughly understood. However, during the fiscal year 1916 there were two instances of men wearing apparatus to combat mine-fires with presumably little or no previous training in its use. In another instance

mine the accumulation of hydrogen and nitrogen in each type when the 'oxygen' used was similar to that furnished the various rescue-cars and stations, that is, oxygen mixed with nitrogen up to 3% and hydrogen up to 1.3%. In these tests 170 samples were taken of either the original oxygen or of the air breathed by the wearers, and the tests indicated that oxygen mixed with more than 0.2% of hydrogen, or 2.5% of nitrogen, might prove dangerous for use in mine-rescue apparatus. Because of these tests the Bureau of Mines proposes, in buying oxygen for use on its cars and stations, to specify that the percentages of hydrogen and nitrogen must not exceed the figures mentioned. These tests also served to indicate the efficiency of the regenerator furnished with the Gibbs apparatus.

\*By courtesy of the Director of the U. S. Bureau of Mines.

Because of the war in Europe the German company making the Draeger apparatus has been unable to procure regenerating cartridges from Germany for use in this country, and it has been necessary to manufacture them in America. The Bureau of Mines has tested the efficiency of American-made regenerators. Two types were submitted, one containing granular sodium hydroxide and the other containing sheet sodium hydroxide. Generally speaking, all of these generators proved satisfactory, but those containing caustic soda in sheets and having absorbent blotters in the four upper trays showed the best results; they are now being used in the training work of the bureau. Two tests were made with the Fleuss apparatus to determine whether caustic soda stored for some time in a Fleuss breathing bag was still in condition to efficiently absorb the carbon di-oxide exhaled by the wearer. In one test caustic soda stored for one month in the breathing bag was tested; the caustic soda tried in a second test had been left in the bag for two months. Samples taken at the beginning and the end of the storage period in eight inhalation-air samples taken in the course of the two-hour tests of each apparatus were analyzed. The tests showed that the sodium would still act, as an inhaled air was as high as  $1\frac{1}{2}\%$ . In trials with the Fleuss apparatus, electrolytic sodium hydroxide prepared in the lump form was tested. Eight inhalation-air samples taken in the tests showed the lump sodium to be an efficient regenerating agent. In four tests of the Fleuss apparatus the wearer tried the half-mask, intended for use in fire-fighting, instead of the mouth-piece. The tests indicated that although the half-mask may seemingly have an air-tight fit on a man before he enters the smoke-room, inward leakage may occur after he has been in a noxious or poisonous atmosphere for a short time, so that the half-mask is not as safe as the mouth-piece.

An important series of tests of mine-rescue apparatus was made in Colorado to determine, if possible, whether rescue apparatus possessed defects that rendered it dangerous for use at high altitudes. The first series of tests was made at Manitou, the second at the Half Way House on Pikes Peak, and the third at the summit. The results indicated that rescue-apparatus is not more dangerous at high altitudes than at low. The oxygen supply was sufficient, and, in fact, men wearing the apparatus and getting a constant supply of oxygen from it could make physical exertions of which they were incapable when breathing the natural air because of its being rarefied and containing a less weight of oxygen per cubic foot than the air supplied by the apparatus. The conclusion reached, therefore, was that the probable cause of the excessive number of accidents with rescue-apparatus in mines at high altitudes resulted from neglect in the care of the apparatus, particularly in the renewal of rubber parts that had dried and cracked. A secondary, but, possibly, more important result of these investigations was the comparison of the Gibbs apparatus with the older forms of apparatus, particularly the Fleuss and Draeger, heretofore used by the mine-rescue crews at the

bureau. The results demonstrated that the Gibbs apparatus adapts itself to the wearer's needs far better than the older forms of apparatus. In endurance tests particularly it was found that this automatic adjustment tends to insure a much longer duration of the oxygen-supply and of the power to absorb carbon di-oxide than do any of the other types.

As the Gibbs apparatus, which has been developed by W. E. Gibbs, engineer of mine-safety investigations, in co-operation with other members of the Bureau of Mines, seems in several respects to be superior to other types, a detailed description is here presented. This apparatus is a self-contained unit carried wholly on the back of the user. It is light, and its parts are well protected against injury. A special device feeds the oxygen used, and although plenty is available for the wearer when working hard none is wasted when he is resting; hence the new apparatus may be worn for a considerably longer time without re-charging than other models now in use. An unusually efficient carbon di-oxide absorber that liberates little heat is another feature. Caustic soda, which is much cheaper than the potash salt formerly thought necessary, is used as the absorbent. It is theoretically easy to supply a mine-rescue man two or three hours with an artificial atmosphere from an apparatus of no greater weight than he can readily carry on his back. In practice, however, the construction and operation of such devices offer many difficulties. The knowledge that the failure of any part to respond to the needs of the wearer means his almost certain death places a heavy responsibility on the designer and constructor.

Normal air contains roughly 20% of oxygen mixed with about 80% of nitrogen and a trace of carbon di-oxide. At each inspiration part of the oxygen breathed combines in the lungs with carbon brought by the blood, and the air expired contains about 4% of carbon di-oxide. The nitrogen of the air is unchanged by the act of respiration and takes no active part in it. For all practical purposes an artificial atmosphere of pure oxygen, or oxygen containing only a small percentage of nitrogen, is actually preferable to normal air in the conditions surrounding mine-rescue work. In spite of the general belief that pure oxygen is unsafe to breathe, no abnormal effects attend its use unless it be breathed for a much longer period than that during which rescue-apparatus is customarily worn, and even then the only symptom noted is a slight irritation of the bronchial passages. The amount of oxygen consumed in the body is precisely the same whether the gas be breathed pure or diluted with nitrogen in the form of air. Contrary to the belief held a few years ago, there is no flushing of the face, no feeling of exhilaration, no increase in the pulse-rate, nor elevation of arterial tension. If, however, the oxygen-content of the air breathed be materially reduced, unconsciousness and death are almost sure to follow without any warning symptoms, provided the carbon di-oxide content of the air remains low. For this reason it is advisable that breathing apparatus should supply an atmosphere rich in oxygen. As much of the oxygen made

from liquid air contains 2 to 3% of nitrogen, which remains unchanged and accumulates in the apparatus, analyses of the atmosphere breathed by the wearer generally show a decreasing content proportionate to the length of time the apparatus is worn. If the proportion

THE DRAEGER APPARATUS

of carbon di-oxide in the artificial atmosphere rises much above 2%, deeper breathing or panting warns the wearer of danger, generally in time to let him get to safety.

Under the best conditions the exploration of mines in

THE FLEUSS-PROTO OXY-CYL EQUIPMENT

which there has been a recent fire or explosion is a hazardous undertaking, not only because of exposure to bodily injury but also because no mechanical breathing device can be made so perfect that it will never fail. Frequent inspection of the breathing apparatus and constant vigilance in keeping it in perfect repair reduce the risk of failure to a minimum.

## Screen-Analyses

\*In ascertaining the efficiency of crushing-machines, as well as in the study and control of all hydro-metallurgical processes, small-scale screening tests are of the greatest value. In order that the work of one mill may be compared with that of another, it is necessary that a uniform screen-scale be used by all operators, and, furthermore, that a uniform method of making the sizing test be employed. In the past much confusion has existed, both as regards the screen-scale and the method of making the test, therefore it is often impossible to make such comparisons. It was with the end in view of establishing a standard method of performing sizing tests that this subject was taken up. In brief, the work so far done demonstrates that satisfactory sizing tests may be made either by hand or by machine. It must be emphasized, however, that certain precautions must be observed if consistent results are to be obtained, and, furthermore, it must be expected that considerable time will be consumed in making sizing tests by hand. In the sizing of crushed ores it is essential to remove the finely divided amorphous material by washing prior to screen sizing. If this is done, concordant results can be obtained, but if sizing of the original material without such washing is attempted, the time necessary for the operation is increased by reason of the clogging of the finer screens by the fine material, and, furthermore, the proportion of the coarser sizes is greater, by reason of the fact that the fine clay particles adhere to the coarse sizes. The only way to insure their removal is by preliminary washing, as previously pointed out.

PAINT may be removed from iron and steel surfaces by the following formula prescribed by the U. S. Coast Artillery Corps. The method is used in cleaning the exterior surfaces of the big guns and carriages in coast defences. One pound of concentrated powdered lye is dissolved in six pints of hot water, and enough lime is added to make the solution thick enough to spread. It is applied, freshly mixed, with a brush, and allowed to remain until almost dry. When it is then removed, it will take the paint with it. If the paint is thick and old, wash off the surface and apply a second coat of this emulsion. Before a new coat of paint is put on, the metal should be washed with a solution of one-half pound of washing-soda (sal soda) dissolved in eight quarts of water. The parts should then be thoroughly dried by wiping or warming.

SMOKE or fume consists of a dispersion of solid particles in air, in which, according to W. W. Strong, 50,000,000 may be contained in one cubic centimetre. These dispersed particles consist of small groups of molecules the relation between which, in point of size, and the molecules themselves he states in striking manner as being the difference between the island of Manhattan and the Engineers' building in New York City.

# Copper-Precipitating Plant at Balaklala Mine

By S. A. HOLMAN

Construction on this plant was started on July 1, 1914, the plant being completed and the water turned in on August 7. The design is nearly the same as the larger plant of the Mammoth Copper Mining Co., but it includes several minor improvements suggested by experience. It consists of two towers approximately 4 ft. wide by 10 ft. high by 64 ft. long, there being two decks for holding the scrap-tin and a trough at the bottom for collecting the precipitate. The water flows by gravity through the Weil tunnel, at the outlet of which it enters a flume carrying it to the first precipitating-tower. These towers are filled with scrap-tin which is turned and washed clean of precipitate each day, so as to leave a clean surface for further precipitation. After passing through

MAY 15, 1915. 60 GALLONS PER MINUTE

	Copper Gm. per litre
Water at intake.....	0.2205
Water at discharge first tower.....	0.0826
Water at discharge second tower.....	0.0348

COPPER-PRECIPITATING PLANT, BALAKLALA MINE

the first tower the water flows directly to the second tower, the dripping-flumes of which are on a level with the discharge of the first tower. From the bottom of the second tower the water flows into a tank filled with scrap-iron and thence to waste.

The settling-tanks used are round redwood tanks, 12 ft. in diameter and 4 ft. deep, one for each tower, and so arranged that the precipitate can be sluiced into them from the collecting troughs in the bottom of the towers. An average of about 30 gallons per minute is delivered to the first tower, the flow of mine water varying from 25 to as much as 100 gal. per minute during the heavy rains in the spring. This water contains about 0.312 grammes of copper per litre.

Samples of the water at the intake and discharge, taken at regular intervals over a period of one year, indicate a saving of about 90% of the copper-content. A clean-up of the last tank filled with scrap-iron has not been made, but undoubtedly a further saving is obtained there. Those given in the accompanying table are characteristic assays and show the work done by the two towers extracting 88.21% of the copper.

CROSS-SECTION COPPER-PRECIPITATING PLANT

The water is turned out of the towers for one five-hour period during each month when the precipitate is sluiced into the settling tanks. The supernatant water is drawn off and the cement-copper is allowed to dry by evapora-

tion until sufficiently compact to be handled. This precipitate, still containing considerable moisture, is then sacked and shipped to the smelter for further treatment.

The cost of the installation was as follows:

<b>Material:</b>	
Lumber .....	\$212.88
Nails .....	20.60
Oakum .....	1.20
Redwood tanks .....	62.75
Forks .....	1.50
<b>Labor:</b>	
Carpenters .....	132.00
Helpers .....	150.00
Laborers, grading .....	102.09
	<hr/>
	\$683.02

The results of two years' operation are summarized below:

Dry tons cement-copper produced.....	129.2955
Average assay, cement-copper produced....	28.489%
Pounds copper produced.....	73785.7205
Tons scrap-tin consumed.....	150.694
Pounds tin consumed per lb. copper.....	4.08

The total costs for two years were: 150.694 tons scrap-tin, at \$14, f. o. b. Coram, \$2110.87; 24 months' labor at \$70 per month, \$1680, making a total of \$3790.87. Adding the cost of installation, \$683.02, the operating cost was \$4473.89. The total net receipts for precipitate for this period were \$14,877.77, showing a net profit of \$10,403.88 or an average of \$433.49 per month. The average price received for copper during this period was 24.456c. per lb. The cost of producing one pound of copper was, labor 2.276c., scrap tin and sundries 2.861c., being a total of 5.137c. It is interesting to note that if copper had been selling at 15c. per pound the profits would have been \$4423.26, or an average of \$184.30 per month.

PROTECTION of oil-sands by mud-laden fluid and cement was discussed recently at a hearing by the State Oil and Gas Supervisors and it was generally admitted its effectiveness was not proved. If the method can be perfected and demonstrated it will result in an enormous saving of expense for casing and drilling. Rules governing tests of the method have been formulated by the California State Mining Bureau, but only one company has volunteered to make such a test. Most operators in the immediate vicinity of Taft are using at least two strings of casing for the protection of oil-sands against water and they propose to continue the practice.

ELECTRIC STEEL is now being produced in this country at the rate of 200,000 tons per annum, and the rate of increase in the capacity of the plants for making it indicates that the output next year will exceed 300,000 tons. America is already in the lead as a producer of electric steel, notwithstanding the fact that hydro-electric power is high as compared with such countries as Norway, where it is available, under wise government control of water-powers, at prices as low as \$6 per horse-power year.

## Potash Market

The potash market is only fairly active, the farmers buying slowly on account of the prevailing high prices. Nevertheless there is no difficulty in disposing of potash products in car-load lots, and it would be easy to contract for steady deliveries at good prices. The market standards and the corresponding prices for immediate delivery at the middle of July were as follows:

<b>In bags, on the basis of 80%:</b>		<b>Per ton</b>
Muriate of potash, 80 to 85%.....	\$350 to \$360	
Muriate of potash, minimum 95%.....	360	
Muriate of potash, minimum 98%.....	nominal	
<b>Basis of 80%, in bags:</b>		
Sulphate of potash, 90 to 95%.....	\$275 to \$300	
Double manure salts, 48 to 53%.....	105	
<b>In bulk:</b>		
Manure salt, minimum 20% K <sub>2</sub> O.....	\$50 to \$60	
Hard salt, minimum 16% K <sub>2</sub> O.....	40 to 50	
Kainit, minimum 12.4% K <sub>2</sub> O.....	40 to 50	

The German 'muriate,' or commercial chloride of potassium, formerly imported, contained usually between 80 and 85% of the chloride, a typical analysis being potassium chloride 83.5%; potassium sulphate, 0.7%; magnesium sulphate, 0.4%; magnesium chloride, 0.3%; sodium chloride, 1.4%; calcium sulphate, 0.2%; and insoluble, 0.5%. As an indication of normal prices it may be stated that the average paid for imported kainit in 1912 was \$4.66 per long ton, in which year 511,966 tons of this material was consumed in the United States.

PARAFFIN, or a paraffin-bearing oil, on being digested with sulphur at moderate temperature becomes black and heavy and finally passes to a substance resembling solid asphalt, as explained in a recent paper in the Trans. A. I. M. E. by G. Sherburne Rogers. Similarly, if a light asphaltic oil is treated with sulphur it becomes darker and more viscous, finally becoming asphalt. Under laboratory conditions the reaction is accompanied by the evolution of hydrogen sulphide, and in fact an old laboratory method of generating hydrogen sulphide consists in heating paraffin and sulphur in a retort. The sulphur atom, by extracting two atoms of hydrogen from the oil, causes a condensation or polymerization of the hydrocarbon molecule, and this change is reflected in the increase of the gravity of the oil itself as it approaches solid asphalt. A simple example of change through the action of sulphur, from the polymethylene series of the general formula C<sub>n</sub>H<sub>2n</sub>, to the heavier aromatic series of the general formula C<sub>n</sub>H<sub>2n-6</sub>, may be written:

Hexamethylene + Sulphur = Benzene + Hydrogen sulphide.

This type of reaction is taken advantage of in the Dubb process for manufacturing asphalt commercially by heating crude petroleum or petroleum-residue with sulphur. A variety of artificial asphalt known as Pittsburgh flux, made by treating with sulphur the residuum of Pennsylvania petroleum, is described as tough and sticky, and melting only at high temperature.

# Labor Agitators, Mr. Roosevelt, and Others

By T. A. RICKARD

A few days ago I picked up the autobiography of Theodore Roosevelt, a book that I had bought just before the beginning of the War and had read half-way through. Mr. Roosevelt's recent altercation with Mr. Gompers, his frank and timely protest against the mob-violence at St. Louis, also his prompt offer to lead a body of volunteers to France, had re-awakened my admiration for personal qualities that, whether one likes all of them or not, are splendidly American. So I was soon in Cuba fighting the Spaniards with the Colonel of Rough Riders, reading about the Big Stick and the Square Deal, or absorbing a vigorous reformer's ideas of Social and Industrial Justice. This last is the title of Chapter XIII, in which, to my surprise, I found two pages devoted to a criticism or denunciation—it might be considered either—of an article written by me in 1903 while editor of a New York paper called the *Engineering and Mining Journal*. In the issue of November 14, 1903, I had protested mildly and politely, as I thought, against the invitation given by Mr. Roosevelt, then the President, to six representatives of the Butte labor-unions. This is what I wrote:

"It is announced that, upon the invitation of the President, six representatives of the Butte labor-unions will dine at the White House on November 18. This statement, appearing in most of the daily papers, has received but little comment from the Eastern press, although we feel assured that its significance is fully appreciated in the West, where the history and performance of the Butte Miners' Union are only too well known.

"Whether the action of Mr. Roosevelt is prompted by the impulse of hospitality in return for courtesies received by him during his recent visit to Butte, or whether it is due to political sagacity, we do not know, nor does it concern this technical journal; whether the motive be entirely creditable or distinctly blameworthy, we do know that this official recognition of the Butte labor-union is calculated to inflict grievous injury upon the mining industry of the whole country.

"Before issuing dinner invitations to these men it would have been well if the President had requested his detective service to inquire into their antecedents; of course, it is not usual to institute such search into the character of guests, but, on the other hand, it is not customary to invite people of this description to an official dinner at Washington. In default of such an inquiry we can state that what the Clan-na-gael has been to the brutalities of Irish politics, what the Mafia has been in the bloody feuds of the low-born Italians, that the Butte Miners' Union has been to the labor troubles of our Western mining camps. The unspeakable barbarities of the Coeur d'Alene strike, the anarchy

which disfigured Leadville, the assassinations and murders which made Telluride a by-word, the disorders at Cripple Creek, these, every one of these, have received their mainspring and their sustenance from the gang of ruffians who have controlled the union at Butte. If they have been permitted to maintain their organization at Butte City itself, it is only because Marcus Daly used the union to control Montana politics, Clark bribed outright, while Heinze and the Amalgamated were so busy with their cat-and-dog fight that they had no time to spare for the decencies of civilization.

"If ever there was an organization which deserves to be condemned by honest men, it is the labor-union whose leaders are expected at the White House next week. Wherever a mine manager has tried to treat his men humanely and to give each that equality of opportunity to work which is the American's heritage, there this gang of Irish-Austrian-Italian anarchists has sent its emissaries to stir up trouble. Wherever a mining community has been pursuing the even tenor of its way attended by prosperity and quietness, there these agitators have incited foul murders and cowardly assassinations. It is all well known to the mining men in the West, so well known, alas, that it ceases to excite the fierce resentment which it warrants, until once in a while a friend disappears in the dark or is riddled with bullets in broad daylight. At such times, indeed, we feel like moving heaven and earth to see justice done, only to run into an impassable quagmire of muddy foulness which is called local politics! Is the chief executive, a man held by his friends to be the best type of American manhood, is he going to do an act for politics' sake which will be taken as the endorsement of the most un-American tyranny that ever existed on this continent? We hope not, most sincerely."

Shortly after this editorial appeared I had a call from Edwin Packard, vice-president of the Federal Mining company, who had drawn Mr. Roosevelt's attention to the article and had received from him the letter published in the autobiography. This follows:

November 26, 1903.

"I have your letter of the 25th instant, with enclosure. These men, not all of whom were miners, by the way, came here and were at lunch with me, in company with Mr. Carroll D. Wright, Mr. Wayne MacVeagh, and Secretary Cortelyou. They are as decent a set of men as can be. They all agreed entirely with me in my denunciation of what had been done in the Coeur d'Alene country; and it appeared that some of them were on the platform with me when I denounced this type of outrage

three years ago in Butte. There is not one man who was here, who, I believe, was in any way, shape or form responsible for such outrages. I find that the ultra-Socialistic members of the unions in Butte denounced these men for coming here, in a manner as violent—and I may say as irrational—as the denunciation [by the capitalistic writer] in the article you sent me. Doubtless the gentleman of whom you speak as your general manager is an admirable man. I, of course, was not alluding to him; but I most emphatically *was* alluding to men who write such articles as that you sent me. These articles are to be paralleled by the similar articles in the Populist and Socialist papers when two years ago I had at dinner at one time Pierpont Morgan, and at another time J. J. Hill, and at another, Harriman, and at another time Schiff. Furthermore, they could be paralleled by the articles in the same type of paper which at the time of the Miller incident in the Printing Office were in a condition of nervous anxiety because I met the labor leaders to discuss it. It would have been a great misfortune if I had not met them; and it would have been an even greater misfortune if after meeting them I had yielded to their protests in the matter.

"You say in your letter that you know that I am 'on record' as opposed to violence. Pardon my saying that this seems to me not the right way to put the matter, if by 'record' you mean utterance and not action. Aside from what happened when I was Governor in connection, for instance, with the Croton dam strike riots, all you have to do is to turn back to what took place last June in Arizona—and you can find out about it from [Mr. X] of New York. The miners struck, violence followed, and the Arizona Territorial authorities notified me they could not grapple with the situation. Within twenty minutes of the receipt of the telegram, orders were issued to the nearest available troops, and twenty-four hours afterwards General Baldwin and his regulars were on the ground, and twenty-four hours later every vestige of disorder had disappeared. The Miners' Federation in their meeting, I think at Denver, a short while afterwards, passed resolutions denouncing me. I do not know whether the *Engineering and Mining Journal* paid any heed to this incident or knew of it. If the *Journal* did, I suppose it can hardly have failed to understand that to put an immediate stop to rioting by the use of the United States army is a fact of importance beside which the criticism of my having 'labor leaders' to lunch, shrinks into the same insignificance as the criticism in a different type of paper about my having 'trust magnates' to lunch. While I am President I wish the labor man to feel that he has the same right of access to me that the capitalist has; that the doors swing open as easily to the wage-worker as to the head of a big corporation—and *no easier*. Anything else seems to be not only un-American, but as symptomatic of an attitude which will cost grave trouble if persevered in. To discriminate against labor men from Butte because there is reason to believe that rioting has been excited in other districts by certain labor unions, or individuals in labor unions in Butte,

would be to adopt precisely the attitude of those who desire me to discriminate against all capitalists in Wall Street because there are plenty of capitalists in Wall Street who have been guilty of bad financial practices and who have endeavored to override or evade the laws of the land. In my judgment, the only safe attitude for a private citizen, and still more for a public servant, to assume, is that he will draw the line on conduct, discriminating against neither corporation nor union as such, nor in favor of either as such; but endeavoring to make the decent member of the union and the upright capitalists alike feel that they are bound, not only by self-interest, but by every consideration of principle and duty to stand together on the matters of most moment to the nation."

Mr. Packard showed this letter to me and we discussed the subject of it, with the result that he expressed agreement with my views and asked me to write a letter addressed to him for transmission to the President. That closed the incident, and I had forgotten about it until, in my admiration for Mr. Roosevelt, I read his autobiography and found it embalmed there like a fly in the amber of a romantic story. I have no desire to retort at this late date, but the readers of the MINING AND SCIENTIFIC PRESS will, I hope, absolve me from the charge of being a "capitalistic writer" either now or in 1903. I recall several occasions on which an effort to be fair to the workers has drawn the fire of the real representatives of capital upon me. Next, the fact is worth recording that at the time of the Miller incident in the Printing Office, I had expressed hearty and respectful approval\* of the President's action in his refusal to allow a union to force a foreman-printer out of the Government's service.

However, Mr. Roosevelt was not the only one to find fault with my opinion in the matter of that dinner at the White House. His guests took offence. The Butte Miners' Union officially passed a resolution of a vitriolic character condemning me to everlasting perdition. It was a three-page document written in red ink, to simulate blood, and in terms such that my natural modesty would forbid me to quote, even if the thing had not long ago gone the way of such things, into the waste-paper basket.

That is many years ago. Since then many crimes have been committed in the name of labor, and of capital too, and throughout the many outbreaks of lawlessness the two leaders of the Western Federation of Miners have been prominent—William D. Haywood and Charles H. Moyer. In 1908, after the trial of the ruffians that assassinated Governor Steunenberg of Idaho, these two men quarreled, with the result that Haywood organized the Industrial Workers of the World (I. W. W.) at Chicago, while Moyer remained at Denver in control of the Western Federation of Miners, which became a part of the American Federation of Labor. The Metal Mine Workers' Industrial Union, with headquarters at Phoenix, Arizona, is affiliated with the I. W. W., whereas the

\*October 10 and October 31, 1903. E. & M. J.

W. F. M. is now called the International Union of Mine, Mill, and Smelter Workers, this change of name having been made last year. It is not easy to trace the relationships of the various unions, some of which are organized for a particular strike, to be supported by one or other of the larger unions, only to disappear after they have served their purpose. The strike at Butte was managed by the Metal Mine Workers' Union, organized on June 12, 1917, as is recorded on the corporate seal. They made the following demands:

"1. The Metal Mine Workers' Union to be recognized by all of the mining companies of the Butte district in its official capacity.

"2. The unconditional abolition of the rustling-card system, and to re-instate all blacklisted miners.

"3. A minimum wage of \$6 per day for all men employed underground, regardless of the price of copper, as the cost of living demands more of a wage scale to the working-men. Also surface men to receive an increase in wages in proportion to raise of miners' wages.

"4. The mines to be examined at least once each month by a committee, half to be selected by this union and half by the company, the object being to avoid as far as possible fires and many other accidents.

"5. That all men starting in mines shall be shown exits to other mines, so that they shall be able to escape in case of fire or other accidents.

"6. Any member getting seven to 15 days lay-off to be given a hearing before a committee, three to be appointed by this union, and an equal number to be selected by the company. If the offense claimed is not proven, the miner or miners shall be immediately put to work and paid in full for all time lost.

"7. That all bulkheads must be guarded for the safety of miners by having manholes built therein."

These demands are not all unreasonable, even if some of them are impracticable. (1) As to the recognition of the union, I shall discuss that later. (2) The 'rustling card' is a means of identifying a miner, and, of course, of facilitating the exclusion of men known to be trouble-makers. It is irritating to organized labor, because it prevents the 'penetration' of a crew of quiet workers by agitators or union emissaries. The right or wrong of the system resolves itself into the question whether a mining company is to be allowed the right of refusing to employ those that it believes its enemies. Must an employer give work to the first man that offers or is he entitled to discriminate, choosing those that he considers likely to be docile in preference to those that incite their fellows to the making of demands for higher wages or other concessions? (3) A minimum wage of \$6 per day is only 25 cents above the recent pay, which, however, is arranged by a sliding scale, itself based on the price of copper, starting at 15 cents per pound and \$3.50 per day. (4) The demand for an examination of the mines, to ensure the safety of the men, by a joint committee, is prompted by the recent underground fires at Butte and by the assertion that the State Mine Inspector is not competent. That the mine-fires were of incendiary origin

is believed by the managers and the men alike, and there is reason to infer that the men have their own reasons for coming to this conclusion. Whether the State Mine Inspector in Montana is competent, or not, we do not know, but it is a fact that this kind of official in our Western States may be in sympathy with the capitalist or with the worker in accordance with the leanings of the Governor that appoints him. He may be selected from the ranks of the labor-union or he may be selected on account of his antipathy to organized labor—more correctly, to the turbulent element in the organization. (5) The suggestion that the men should be shown the exits to other mines is reasonable; nor is it obvious why manholes should not be made in the concrete bulkheads separating adjoining mines, except for the possibility of their being left open at the wrong time as well as in moments of danger. (6) The lay-off clause is intended to protect a man from the arbitrary action of a foreman, sometimes due to graft.

The I. W. W. movement is altogether different in kind, as a recent circular, issued by the Metal Mine Workers, will show; it is a long statement, but I give it verbatim, so that the reader may study it at his leisure.

"The Metal Mine Workers have long represented the militant portion of labor in America. They have always given freely of their money, strength, and even of their blood to further the interests of their class, the working class.

"Though the miners have always been militants, it has been years since they have had any form of militant organization. The organization in which they have been organized, or semi-organized, in the past few years has been owned and controlled directly by the greedy mining corporations whom they were supposedly organized to combat.

"But the miner has awakened from the state of indifference and lassitude that has been his in the past. He now demands a real union, and he has it. It is Metal Mine Workers' Industrial Union No. 800 of the Industrial Workers of the World.

"The organization comes clear-cut and says to the world at large that it is after shorter hours, more wages, and better conditions today, while tomorrow we will be satisfied with no less than the complete ownership of the mines, mills, and smelters. Of course, an organization such as this is bound to meet with opposition.

"The mine-owners see in the success of this organization their final doom. The labor skates see in the growth of this organization the vanishing of their pie-cards. The apostles of law and disorder know that this organization means the end of their period of misrule. So this holy trinity combines and fights with every weapon at their command this new and growing body of men.

"But they cannot crush it. It is here. It is here to stay. Thousands are already in its ranks and applications for membership are pouring in by the hundreds. You, Mr. Digger, and you, Mr. Mill or Smelter Worker, should be in its ranks also, if you are not already there. The time is coming when you will be there. Why not

now? It is the organization that you will eventually join. It voices your hopes and aspirations. It is your hope of freedom from the yoke of economic serfdom that has enthralled you in the past.

"It is the Industrial Union. Quasi-industrial unions have sprung up in the mining industry, such as the United Mine Workers of America and the Western Federation of Labor, but they never have functioned as industrial unions. In the United Mine Workers of America district organizations have killed every attempt of the miners to show their militant spirit. One district would strike, while other districts would remain at work furnishing the market with coal. Time after time the workers have been virtually sold out, and the only thing that has kept the U. M. W. A. together is the check-off system whereby the company collects the union dues. Any time the company collects the dues for the union it is dead certain there is something in it for the company. The Western Federation of Miners, while it has had its bright spots in the history of the militant working class, is now decadent. It has lost its once militant membership, and its officials today are spending more time in legislative halls and company offices than they are at the mouth of the shaft. It has lost its punch. All of the red blood that once was in that organization has come into Metal Mine Workers 800 and the headquarters of 800 has more W. F. M. cards that have been turned in lieu of initiation fees than are being carried in the pockets of W. F. M. men throughout the country.

"The I. W. W. is the union for you as a digger to belong to. It is not an organization to restrain your rebellious spirit, but it realizes that you who work in the mines know the conditions in the mines best, and it is you who should determine when to strike and how to strike, and not some set of officials holding down an office chair. It is your union for you to use to better your condition.

"It is the union that is going to get the pay-dirt for the miner. We are starting out with real modest demands. These demands will be multiplied as soon as we have the power to enforce more demands. Among the demands that we want at once are these:

"First: A six-hour work day. Down in the hot stopes a decree has gone forth that six instead of eight hours shall be the length of a shift. That decree, backed up as it is by the organization, must be complied with.

"Second: No less than two men on a machine. This demand is exceptionally modest. Years ago we worked two men to a machine, and today, after 24 years of W. F. M. organization, one man to a machine is the rule. In the drifts and cross-cuts we have held our council and have decided to abolish that rule. Our decision, backed by real organization, must be the law.

"Third: No more speeding up. Too many of our fellow workers are rustling on the hills now. By the curtailment of production we not only will make life more bearable for ourselves, but we will also provide more jobs for the boys rustling on top of the hills.

"Fourth: The abolition of the physical examination.

We do not propose to be stripped before going to work and then be stripped again when we get our pay check. One of the strippings must be abolished now. We will tend to the other one later.

"These demands are only starters. When we get to making and getting our demands in earnest we will make the boss squirm. In fact, he is squirming now with anticipation. We want no more local strikes. Our future strikes will be industrial in scope, embracing not a locality, but an industry.

"Our form of organization provides for the admittance into our ranks of every person working in the mining industry, regardless of creed, color, or nationality. Industrial Union 800 covers the entire mining districts of the West, from Alaska to Mexico. We have branches in every important mining camp. In the smaller camps we have delegates who represent the organization. There is one in your camp. See him, or write to headquarters and we will give you any and all information that you require.

"Now is the time. Arizona is teeming with agitation. Utah, Nevada and Idaho are doing wonderful work. Butte, Montana, is a tower of strength for the new union. You need its help. It needs your help. Send in your application today. The initiation fee is \$2. The dues are 50c. a month. Organization is the key to success. When we are organized, then, and not until then, can we come into our own, the ownership of the earth."

This programme has been further expounded by Haywood, who stated at Chicago, on July 26: "We will go on and on until we—the roughnecks of this world—will take control of all production and work when we please and how much we please. The man who makes the wagon will ride in it himself. Hell! What's the use of talking about anything but the man who works with his hands."

This is the milk in the cocoa-nut. It is the true inwardness of the I. W. W. movement. This organization is not socialistic, of course, but anti-social. It represents a revolt not against the tyranny of capital or the prejudice of class but against any sort of orderly industry. "The man who makes the wagon is to ride in it himself," but who is to furnish the energy to move the wagon?

The I. W. W. demand for higher wages is not based on any idea of just compensation for work, but as a step toward the confiscation of property. The insistence upon two men handling a machine-drill when one man suffices is an attack on the efficiency and economy upon which successful industry is based. So likewise is the protest against 'speeding up'; this places a premium on laziness and incapacity; it is an effort to level down, in anticipation of the time when all the "roughnecks" may sit in the wagon, doing nothing, while a donkey pulls that wagon down a steep place into the sea. The objection to a physical examination before a man is engaged for work that requires healthy vigor is against the true interest of the worker. For example, a man with a weak heart should not be allowed to work where contact with electrical machinery may prove fatal to him, although not fatal to a normal man. The second examination is made, obviously, to prevent false claims for injury during the

time of employment. Both of these medical examinations are in the interest of honest labor.

The Metal Mine Workers at Butte are playing second fiddle to Haywood. In a recent bulletin they claim that the labor unrest all over the country "means that before the end of the War the United States will be operating on the German plan of State socialism, or the ownership and operation by the Government of all public utilities. It means the end of the capitalistic system of society and the inauguration of a new order." The capitalistic system has many obvious defects, but no German alternative is likely to be popular just now, and the suggestion of it argues that lack of humor which is so close to criminality. Indeed this touch is circumstantial evidence of German propaganda. In Germany Mr. Haywood and his rabble would get short shrift; it is only the good-natured tolerance of a democracy that permits such antics.

We may disregard the I. W. W. and the like of them, but we cannot ignore the reasonable insistence of the workers on the right to collective bargaining and co-operative effort in the form of a union. The mine-owner will break his teeth on that bone of contention, for he himself co-operates with his neighbors in the same district, and even in other districts. The refusal to recognize foreign unions is another matter. In that the mine-owner may be right, as he is undoubtedly justified in refusing to deal with the representatives of an organization that has been proved to be a murderous conspiracy or an anarchistic gang. Again there is the question of responsibility. Agreements made between mining companies and labor-unions are of small value because the union is not incorporated, it has no financial responsibility, and may vanish into thin air when asked to make good. It has neither property nor legal entity. On the other hand, the company is incorporated, so that it can be held subject to legal process; it has property, which can be attached on a verdict for damages. It is bound by its contract; the union is not. In consequence, the personnel of the union changes from time to time, in accordance with the spirit of the men; when everything is smooth and quiet the representatives of the law-abiding element are in control, but as soon as trouble begins they are ousted to make room for the rowdy element. If necessary, a new union is organized, usually at the instigation of a Moyer or a Haywood, who pulls the strings from Denver, Chicago, or some other distant point. What is needed is a better recognition of social justice and a more evident effort to play fair, on both sides. Most of these labor-troubles arise from injustice, plus ignorance. The mining companies would be better advised if they co-operated with the Labor Department of the Government and with any other agency that aims to do justice between the employer and the employee, and if they appealed to public opinion by publishing the facts in each case frankly. The members of the mining profession should recognize their duty, as good citizens and as men of education, not to lend themselves to the greed either of the capitalist or the worker, or to the anti-social aims of either, but to do justice as best they

can. After all what is democracy except the maintenance of a recognition of the other fellow's point of view. Neither the Marcus Daly type nor anarchists like Haywood see anything beyond the tips of their noses. That is why in all this anarchistic propaganda the Butte union is "a tower of strength," as the I. W. W. circular says. I conclude by regretting that the First Citizen of the Republic should have invited the representatives of the Butte Miners' Union to dine with him at the Executive Mansion in 1903.

BORON is being experimented with in a matter that is highly suggestive of the stabilization of carbon in the hardening form in steel by those elements that perform the function of retarders of crystallization. Recently N. Tschischewsky investigated this subject, and presented interesting conclusions in the British Iron and Steel Institute. He used boron for case-hardening steel, both as pure amorphous boron and as a finely powdered ferro-alloy containing 19% boron. The iron used in the experiments had the following composition:

	Per cent
Carbon .....	0.12
Silicon .....	0.02
Manganese .....	0.16
Phosphorus .....	0.06
Sulphur .....	0.04

The pieces of soft iron used were cubical and were drilled to the centre, the holes then being filled with the boron or the ferro-boron. The holes were closed with iron stoppers forced home with a hydraulic press. These test-cubes were heated in a Herâeus furnace packed into silica tubes, the air having been removed from the tubes by a mercury pump. It was found that the cementation was accomplished more easily by ferro-boron than with pure boron. The hard white layer of the case-hardened portion was shown to consist of compact boric pearlite, with a twin-crystal structure, and the edges to contain a sub-eutectic alloy of ferrite-pearlite, the ferrite holding the boron in solid solution. The case-hardened part of the specimen shows dark bands representing an alloy of iron with carbon in the vicinity of the ferro-boron.

It is generally recognized that anticlines or arches in the rocks are the most likely places to find petroleum and natural gas, and all such places are now being tested. In consequence, the U. S. Geological Survey, after an examination by A. J. Collier, is calling attention to the Bowdoin dome, near Malta, in north-eastern Montana. It is a broadly arched part of the earth's crust from which the rocks dip away slightly on all sides. It is on the main line of the Great Northern railway east of Malta. Natural gas has already been found there in some wells drilled for water, and a deep well has been begun which should determine whether the dome contains oil. The gas already found is supposed to have been contained in the Eagle sandstone, at a depth of about 600 ft., and it is possible that oil might be found in sands near the base of the Cretaceous rocks, about 1500 ft. lower.

## Recent Patents

1,227,781. PROCESS FOR RECOVERING POTASSIUM SALTS FROM ORGANIC CARBONACEOUS MATERIALS. Franklin C. Grimes, Idaho Falls, Idaho. Filed Aug. 19, 1916.

1. The process of recovering potassium salts from organic carbonaceous materials which consists in placing the material in an open chamber and incinerating the same, and adding a material which, under the action of heat, will liberate sulfur oxide gases to convert the potassium chlorid in the material into potassium sulfate.

2. The process of recovering potassium salts from organic carbonaceous materials which consist in incinerating the same in an open chamber and under a forced draft, and adding sulfur to liberate sulfur oxide gases which penetrate the material during the burning and convert the potassium chlorid existing therein into potassium sulfate.

1,231,707. APPARATUS FOR TREATING ORES AND THE LIKE. Niels C. Christensen, Jr., Salt Lake City, Utah, assignor, by mesne assignments, to Holt-Christensen Process Co., Salt Lake City, Utah. Filed Mar. 30, 1915.

An apparatus for leaching and sedimentation comprising a vertical cylindrical tank having a central discharge opening in the bottom and an overflow rim launder at the top and with a series of stationary horizontal decks disposed one above another therein, alternates of said decks being open respectively at the centre and at the periphery, pipes connecting openings in the periphery of the upper deck with the space above one of the lower decks, a central vertical revolving shaft supplied with arms carrying rables above each deck and above the tank bottom, and so arranged as to move the material upon said decks to the above mentioned openings in said decks and discharge said material upon the decks below and finally discharge said material through the above mentioned discharge openings, and means for feeding ore and other substances into the upper part of the tank.

1,232,553. PROCESS OF PRODUCING FERTILIZERS FROM SILICATES. Louis L. Jackson, New York, N. Y., assignor of one-half to Odus C. Horney, New York. Filed June 16, 1916.

The process of producing a fertilizer or fertilizer base which comprises treating silicates containing alkali metals and aluminum with calcium hydrate and water and subjecting the mixture to heat and pressure; separating the aqueous

solution from the insoluble and sparingly soluble constituents and treating the solution with an acid thereby forming alkali metal salts and drying; subjecting the said constituents to treatment with an acid in quantity at least sufficient to convert all the calcium present into a calcium salt and set free the aluminum as a hydrate, and separating the liquor; again treating the cake with an acid in quantity sufficient to dissolve the aluminum hydrate and separating the liquor; and mixing the cake with the alkali metal salts to form the fertilizer.

1,232,111. ROCK-DRILL. Michael Smith, Bisbee, Ariz. Filed Sept. 28, 1916.

1. The combination in a rock drill adapted to a drill iron having an axial bore therethrough, a tappet having an axial and a lateral passage, and a bushing having a passage connecting the exterior with the interior thereof; of a packing consisting of a channeled ring of perforated flexible material having its open side toward said tappet lateral passage and its perforations toward said bushing passage, and a channeled ring therein of perforated metal having its open side toward said bushing passage and its perforations toward said tappet lateral passage.

2. As an article of manufacture, for use in a rock drill, a packing consisting of a channeled ring of perforated flexible material, and a channeled ring of perforated metal having its open side adjacent the perforations in said flexible ring and having its perforations adjacent the open side of said flexible ring.

1,232,977. METHOD OF UTILIZING FELDSPAR. John Gustaf Adolf Rhodin, Chiswick, England. Filed Dec. 4, 1915.

1. The method of utilizing potash feldspar which consists in mixing the ground feldspar with a small quantity of a sodium salt, causing a mixture of sulfur dioxide, steam and air to react on the heated mixture, collecting the sulfuric acid formed in suitable receivers and leaching the residue so as to obtain sulfate of potash and to leave a residue suitable for making white Roman or Portland cement.

2. The method of utilizing potash feldspar which consists in mixing the ground feldspar with a small quantity of sodium chlorid, causing a mixture of sulfur dioxide, steam and air to react on the heated mixture collecting the sulfuric acid formed in suitable receivers and leaching the residue so as to obtain sulfate of potash, and to leave a residue suitable for making white Roman or Portland cement.

1,232,611. FILTER-PRESS. Charles Marshall Saeger, Jr., Palmerton, Pa. Filed July 11, 1916.

1. In a filter press, the combination of a longitudinally movable tank having an open end, a closure therefor fixed against movement, a plurality of spaced filtering elements having smooth vertical faces secured on said closure and projecting toward said tank, said filtering elements being adapted to enter and be withdrawn from said tank as the latter is moved, and a plurality of vertical wires crossing the open end of said tank and adapted to engage the vertical faces of the filtering elements and automatically clean them of collected solid matter when the tank is retracted.

1,232,754. MEANS FOR MOUNTING AND DRIVING CENTRIFUGAL MACHINES. Melville H. Barker, Boston, and Comfort A. Adams, Cambridge, Mass.; Annie M. Barker, administratrix of said Melville H. Barker, deceased; said Adams and administratrix assignors to American Tool & Machine Company, Boston, Mass. Filed Apr. 22, 1910.

1. In a centrifugal machine the combination of a rotary gyratory basket-shaft and oscillatory bearing sleeve in which said shaft is suspended for support and rotation, a non-oscillatory motor-driven shaft arranged axially above said basket-shaft, flexible connecting means forming a driving coupling between the adjacent ends of the two shafts, said connecting means being unyielding in a circumferential direction while yielding freely for a slight distance in a radial direction, whereby the torque of the motor shaft may be transmitted to the gyratory basket-shaft without lateral strain on the motor-shaft, substantially as described.

2. In a centrifugal machine the combination of the oscillatory sleeve, a thrust bearing located therein in the plane of its centre of oscillation, a basket shaft suspended from said thrust bearing and having lateral bearing support in the lower portion of said sleeve, said shaft being divided transversely into upper and lower sections provided at their adjacent ends with opposed coupling flanges, means for detachably connecting

said flanges together, an oil cup supported by the flange of the upper section by a detachable connection to extend upward outside of said sleeve beyond the plane of said thrust bearing, substantially as described.

1,233,149. ORE-CONCENTRATING TABLE. Enos A. Wall, Salt Lake City, Utah. Filed Oct. 16, 1916.

1. An ore concentrating table of the longitudinally differentially reciprocating type formed of a series of flat topped sections, each section having all its top surface in a plane common to all, and provided with parallel channels intermediate the sections extending from the head to the foot end of the table and open at the said foot end for the continuous discharge of the mineral concentrates; the said channels being of the same depth and width throughout and having their lower side walls inclined from the bottoms of the channels outward from end to end at an angle oblique to the flow of the wash water.

2. An ore concentrating table of the longitudinally differentially reciprocating type provided on its upper surface with a series of parallel channels extending from the head to the foot end of the table and open at their foot ends for the continuous discharge of the mineral concentrates, and hoods forming the upper surface of the table and projecting at one longitudinal edge over the upper sides of the channels and extending throughout the length of said channels, all portions of each hood member lying in a plane common to all the hoods of a table section.

1,231,967. ELECTROLYTIC RECOVERY OF METALS FROM THEIR SOLUTIONS AND IN APPARATUS THEREFOR. Urlyn Clifton Tainton and Malcolm Foerster Lambe Aymé Aymard, Johannesburg, Transvaal, South Africa. Filed Nov. 14, 1914.

1. Apparatus for recovering metals from their solutions electrolytically comprising alternate anode and cathode elements, each cathode element comprising a porous conducting support, a coating of comminuted conducting material deposited on said support from a liquid carrying said material in suspension, means for passing the metal bearing solution through the pores or interstices of said comminuted conducting substance, and means for drawing off the comminuted conducting substance after it has been detached from said porous conducting support.

5. Apparatus for recovering metals from their solutions electrolytically, comprising alternate anode and cathode elements separated by porous diaphragms, each cathode element comprising a porous support having thereon a coating of comminuted conducting material deposited from the solution, means for adding the comminuted conducting material to the inflowing solution, means for passing the metal-bearing solution through the interstices of said coating, and means for withdrawing the comminuted conducting material after it has been detached from said porous support.

# REVIEW OF MINING

*As seen at the world's great mining centres by our own correspondents.*

## METCALF, ARIZONA

THE LABOR SITUATION IN GREENLEE COUNTY REMAINS UNCHANGED.—MINERS LEAVING THE DISTRICT.—AN OPEN LETTER.—A LACK OF INTEREST SHOWN BY WORKMEN.

There has not been much change in the strike conditions in the Clifton-Morenci-Metcalf district since the strike was declared and the men walked out, July 1. The men for the most part are loafing on the streets, apparently being supported by money furnished by the unions. However, the strike has seriously affected all classes of business; hotels report they are not making expenses; the merchants are doing very little; and freight-trains are limited to two a week. Hence, at times, there is a shortage of some staple or other. The Americans who stayed with the companies have had their salaries cut 25% and consequently are seeking other positions and are leaving as fast as they secure them.

Among the demands of the strikers is the Miami wage-scale, and Norman Carmichael, general manager for the Arizona Copper Co., has issued a pamphlet to the public as well as to the employees, which shows up the wage-question clearly. The following is taken from this pamphlet:

"In Miami in the month of May, 1917, there were mined by the Inspiration and Miami companies a total of 777,220 tons of ore, or 25,071 tons per day. The total number of men employed in their mining departments by these two companies was 1875, or a yield of 13.4 tons per man per day.

"In the Clifton-Morenci-Metcalf district, the three companies, Arizona, Phelps-Dodge, and Shannon, together mined 6710 tons per day and employ in their mining operations 3730 men, equivalent to a yield of 1.8 tons of ore per man per day.

"While it is true that the above difference in the yield per man is essentially due to the different conditions in the two districts, another factor comes into play, for it is also a fact that mining labor in this district is not equal in efficiency to the labor in other districts, nor are our miners as efficient as they were a few years ago.

"An extract from the records of one of the operating companies may be given as illustrative of this unfortunate condition.

"In the mine in question some 600 men are employed and while no change has been made in mining methods employed, which would account for any diminution of the output per man, the following figures show the facts:

	Tons per man per shift	Average wage per shift
1914 .....	2.52	2.30
1915 .....	2.60	2.34
1916 .....	2.22	3.72
1917 .....	2.18	4.12

"Thus, while wages have steadily and rapidly advanced during the past four years, the average output per man has steadily declined.

"During 1915 many of our best miners left the district and the companies here are handicapped by the necessity of using a large number of men, some of whom are not physically able and others who are not mentally disposed to turn out an average day's work, and while there are many employees in our mines to whom this remark does not apply, inquiry among various foremen and shift-bosses in charge of the operations in the mines will corroborate this statement.

"The attitude of a certain important section of the mine employees toward their superiors has also been anything but satisfactory for some time past. The deliberate opposition

MILL AT THE MIAMI, ARIZONA

shown to any method introduced for the purpose of increasing efficiency, the spirit of insubordination and the lack of co-operation and loyalty, are factors not conducive to the harmony and good feeling which should exist, and unless the companies can be assured of a better spirit and heartier co-operation with them among their employees there is little inducement to re-open the mines."

## AJO, ARIZONA

LARGE FLOTATION PLANT AND SMELTER FOR AJO.—OXIDIZED ORE SUFFICIENT TO CONTINUE LEACHING FOR TEN YEARS.—THE GREAT VERDE MINE STRIKES SULPHIDE ORE.

John C. Greenway, general manager for the Calumet & Arizona and New Cornelia Co., has announced that in view of the Ajo Consolidated purchase by the New Cornelia Copper Co., a 5000-ton flotation plant and a 2000-ton smelter will be erected at Ajo. As a result of the purchase of the Ajo Consolidated by the New Cornelia, the ore reserve already developed would reach 21,000,000 tons, the greater part of which will remain untouched for 15 years. The Ajo properties are extensions of the New Cornelia and were developed by extensive mining and diamond-drilling. The moving spirit of Ajo was James Phil-

lips. of New York, former president of the Tennessee Coal & Iron Company.

The leaching-plant of the New Cornelia produced 2,100,000 lb. of copper in July. This plant will have served its purpose in 10 years, at which time it will probably be replaced by the addition of another 5000-ton unit to the flotation-plant for the oxidized ores that are now supplying the leaching-plant at the rate of 5000 tons per day, then will have been exhausted. At the end of two years enough of the oxidized ores will be stripped from the sulphide orebodies to supply an equal tonnage of sulphides to the first unit of the flotation-plant, which, by that time will have been completed. The New Cornelia Copper Co. is shipping some oxidized ore to the smelter at Douglas. The ratio of concentration in the flotation-mill will be 15 to 1, which will provide 750 tons of concentrate per day. To ship this to Douglas would cost approximately \$1,000,000 per year. The alternative, therefore, is to build a smelter at Ajo, which would pay for itself in a year and a half. In the meantime the shipments of oxide ores from both the New Cornelia and the Ajo Consolidated will continue, but the main sulphide orebodies of the latter will be held in reserve, and after stripping the oxides, will be mined to supply the flotation-mill, which eventually will have a capacity of 10,000 tons per day. A considerable tonnage of high-grade ore has been developed at depth on the Ajo Consolidated.

J. W. Hubbard, who is in charge of the operations of the Great Verde property, says that the shaft is in sandstone and limestone, in which are bunches of copper carbonate, chalcopryrite, and copper glance. These bunches of ore are in the sandstone and limestone, and not in the conglomerate. Ore was discovered during the sinking of the shaft, 36 ft. below the collar. This ore is similar to that found in the United Verde Extension on the 800-ft. level. Progress in shaft-sinking is as rapid as can be expected with hand-work, but as soon as machinery is installed, plans for which are under way, the work will be pushed.

## ALASKA

MINERS AT KENNECOTT DEMAND SAME WAGES AS ARE PAID IN THE INTERIOR PLACER MINING DISTRICTS.—NEW STAMP-MILL FOR SEWARD PENINSULA.—THE KENNECOTT RAILROAD NOW OPERATING AT A PROFIT.

George E. Baldwin has gone to his copper property in the Copper River valley to do development work. W. R. Rust, of Tacoma, who is the principal owner of the Chichagoff mine, is making his annual inspection of the property. R. E. Hutchinson, secretary of the Hirst-Chichagoff Mining Co., will spend some time at the property. Extensive development work has been planned for the summer. William Conley, president of the Valdez local of the Western Federation of Miners, has sent out telegraphic information that there is no labor strike at Ellamar and that none is contemplated. It is also reported that there is no trouble at Latouche, a Kennecott property. The Kennecott miners claim that that property is an interior mine and therefore that the same wage-scale should be paid as in the placer fields of Fairbanks, Iditarod, Nome, and elsewhere. Bennett T. James, formerly of No. 17 Below Goldstream, Fairbanks, has taken in a stamp-mill which he and John Ronan will place on their property on Moss Pass near Seward. This will be the first mill in that district.

The high prices for copper, and the record shipment of ores and concentrate over its lines have now transformed the Copper River & Northwestern Railway, controlled by the Kennecott Copper Corporation, into a profitable enterprise. The capitalization against its 196 miles is \$27,837,400. The road started operation in 1911 and from November of that year to the end of May, 1916, it piled up a deficit of \$2,941,962. But during the period from July 1, 1915, to May 3, 1916, it showed a surplus of \$487,000 after deducting interest charges. In every year but one it has shown a substantial margin above

operating expenses, but the interest charges have been so heavy that the road was unable to produce a surplus before 1916. Mr. Stannard, superintendent for the Kennecott company, returned to Kennecott on July 26, intending to adjust the grievances of the miners. He offered a new sliding-scale, equivalent to 25c. per day more than the old rate. The men had demanded to be paid a flat-rate, the same as at other Alaskan mines. The highest wages they could hope for under the sliding-scale were less than the desired flat-rate and they refused to consider it. On July 30 the Kennecott officials visited the miners' camp at Blackburn and tried to reason with them, asking if the company had not kept its agreement with them; also informing them that the present Kennecott scale was 10% higher than that at either Butte or Bisbee. The men object strongly to the sliding-scale, which keeps them constantly in doubt as to their rate of pay. For instance, in May and June wages dropped 25c. at the time when they were advancing elsewhere in Alaska. As the Kennecott miners are mostly Alaskans, accustomed to wages based on the gold standard, they were opposed to such an arrangement, and demanded a fixed scale of wages last December, but were over-ruled. This is the fourth wage dispute in 18 months and the miners have appealed to the Government for a board of arbitration to settle the matter. The mine management, on the other hand, feels that it has not been fairly treated, because they entered into an agreement with the miners that was to continue throughout the year 1917. Mr. Stannard said that he had hardly left the mine before the miners, in violation of their agreement, served notice on the assistant superintendent, Mr. Smith, demanding an increase in wages, and the abandonment of the bonus-system for the flat-wage, similar to that paid to the placer-operators during the summer in the interior, where wages are \$5 per day with board. Under the bonus-plan laborers were making \$5.25 per day and higher, and paying \$1.25 per day for board. It is said that some of the miners made as high as \$5.25 per day clear. The mine management, while claiming that the miners had no right to break their agreement to adhere to the old wage-scale throughout the year 1917, conceded that there was reason for a small increase in wages, but refused to permit men who were responsible for the agitation to return to work. Telegraphic advices from Washington (July 14) say that the miners who participated in the Kennecott strike have yielded to Secretary of Labor Wilson's request that they resume work, pending the arrival there of Labor Department mediators. Advices from Fairbanks state that Marshall L. T. Erinn has arrived from Nenana, having in custody three men charged with being ringleaders in the labor trouble at Nenana, and also charged with sedition. It is not known whether the latter charge will be pressed, but the three men will be interned in the Federal jail until the end of the War. Marshal Erinn will return to Nenana and promises to arrest other aliens unless they obey the law. The strike is over at Nenana and the men have returned to work.

## PACKARD, NEVADA

RAPID MILL CONSTRUCTION AIDED BY MODERN METHODS.—ELECTRIC MOTORS FOR TRANSPORTATION.—IMPORTANT DEVELOPMENT OF SULPHIDE ORE.—PROSPECT OF ANOTHER APX SUIT.—TUNGSTEN DISCOVERIES.

The erection of the framework of the Rochester Combined 300-ton mill is nearing completion, and sets a new record in rapid mill-construction. Compressed air is used in boring all timbers, and in driving ship-spikes. A Little Tugger hoist is used in placing timbers. Two shifts of carpenters are employed, the night-shift working by electric light. About 500,000 ft. B.M. of timber will have been used. In spite of the scarcity of supplies, the constructing engineer, K. Freitag, believes the mill will be completed by November 1.

The Combined is pushing development on several parts of

the property. Most of the work is being done on the main fault-contact between the rhyolite and rhyolite-tuff, on which the principal Packard orebodies lie. Some ore has been developed by five adits—the Shepherd No. 1 and 2, and Links No. 1, 2, and 3—for nearly a mile along this contact, the ore occurring as lenses in the rhyolite with tuff hanging wall. The Happy Jack shaft at the south-west end of the property is now down about 200 ft. on the dip of the vein. The ore from this shaft is to be hauled to the mill by electric locomotives. Tramways will deliver the ore from the Link Tunnels. A Sullivan 600-cu. ft. angle compound-compressor is now being installed, replacing the 6-drill portable Diesel-engine driven machine. The latter will be used in prospecting the outlying claims. The company is now beginning the making of a topographic map of the property, to be followed by a thorough geological examination.

The Walker adit on the Packard property is being advanced to connect with the Combined company's Shepherd No. 1 adit, and to open that part of the Shepherd orebody lying in Packard ground. A cross-cut from the 120 Tunnel recently cut a vein of sulphides nearly 25 ft. wide, showing good milling ore throughout. The same orebody was later cut on the 160-ft. level. Drifts are being run to determine its lateral extent. The finding of primary sulphide ore simultaneously in the Packard and Rochester mines was one of the most interesting developments of the past few months. Heretofore the value of the ore was almost entirely in hornsilver. It is probable that a shaft soon will be sunk to open this vein in depth. Pending the installation of a new 100-hp. motor for driving the tube-mills, the Packard mill has been shut-down for a few days.

On the Nones claims the owners have opened up a promising vein. These claims adjoin the Happy Jack group, of the Combined property.

The Packard district was recently visited by Adolph Knopf, of the U. S. Geological Survey, and a bulletin will probably be issued soon as a result of his investigation. The geology of the district was also studied by Mr. Jones, of the University of Nevada. The Nevada College of Mining Summer Camp was established on the Packard property.

The Adams vein on the 800 and 900-ft. levels of the Rochester Mines Co., at Rochester, is yielding excellent ore. This is the sulphide orebody previously referred to. No mention is being made by any of the companies regarding the threatened suit involving the Rochester Mines Co., Merger, and Nenzel Crown Point, but the recent visits to the district of Lawson, Searls, Emmons, and other geologists indicates that another big apex-law battle is about to begin.

A number of the larger stockholders of the Packard Mines Co. have bought the Nevada Austin mines at Newpass, 25 miles from Austin, and have begun the erection of a 75-ton mill and cyanide-plant. The ore is free-milling, gold predominating. Tests have shown it to be amenable to cyanidation, excellent extraction and recovery having been obtained on 80-mesh material. The flow-sheet is similar to that of the Packard mill, except that a Blake crusher will be used and rolls eliminated. The ore will go direct from the Blake crusher to a 6 by 16 Hardinge ball-mill in closed circuit with a Dorr classifier. A Dorr thickener will precede the Dorr agitator, followed by modified C. C. D. in a second set of thickeners, these to be followed by an Oliver filter. Merrill presses are to be used for precipitating, and a Monarch tilting-furnace for refining. A 150-hp. Diesel engine will furnish power. It is the intention to utilize the exhaust for heating mill-solutions. Frank Margrave, of Reno, is president and general manager of the company. Douglas Muir is constructing engineer.

A promising tungsten prospect is being developed near Oreana by E. H. Radtke. The tungsten mill at Toy is shut-down, but the plant at Toulon is in operation. Toy and Toulon are two small stations on the Southern Pacific railroad a few miles below Lovelocks.

## CRIPPLE CREEK, COLORADO

CRESSON CONSOLIDATED'S HIGH-GRADE SHIPMENTS.—LESSEES WORKING OLD DUMPS AT A PROFIT.—LESSEES BREAKING HIGH-GRADE ORE.—WATER INCREASES IN THE ROOSEVELT TUNNEL.—DIVIDENDS IN AUGUST.

High-grade ore from the new east vein at the 1400-ft. level of the Cresson Consolidated mine, comprising three consignments of 90 tons each, sent to the Golden Cycle Mining & Reduction Co. at Colorado Springs, returned a gross bullion value of \$153,000. One lot carried \$400 per ton gold, lot No. 2, \$500 per ton, and Lot No. 3, \$800 per ton.

The shoot has now been proved for 125 ft., and the ore mined was taken out in driving the drift 8 ft. wide. The management is proving the vertical continuity of the shoot by raise and winze.

The July production from the Elkton mine of the Elkton Consolidated Mining & Milling Co. totaled 33 cars of mine ore, valued at \$18 to \$20 per ton. This production was made by 22 sets of lessees. The Tornado mine of this company under lease to Whittenberger and Collins, is again on the shipping list with a car per week. The ore mined at the 3rd and 6th levels is of about one-ounce grade.

Dump lessees who shipped heavily from the Gregory dump, have loaded out from 75 to 100 cars to the Golden Cycle mill at Colorado Springs. This ore is carrying gold not to exceed \$8 per ton. The main Elkton mine dump is producing a car per week of \$12 to \$15 ore.

The output from the El Paso Consolidated on Beacon hill was light. There are 16 sets of lessees, who produced 550 tons, estimated at between \$18 and \$20 per ton. The company is still inactive, new development being dependent on the work of lessees.

The Queen Bess mine, on Tenderfoot hill, now owned and operated by Hahnwald Olsen & Company, who took up the option at \$17,500, on the property, are shipping steadily, and last week 1200 lb. of sacked ore shipped to the Eagle Ore Co.'s sampler, brought settlement at a rate in excess of \$1 per pound. There were seven cars of ore loaded out last week of better than 2-oz. ore. R. M. Gilber, leasing on the Iron vein of the El Paso Gold King mine in Poverty gulch, operating through the lower Gold King adit, 1200 ft. from the portal, last week loaded out his initial shipment of milling-grade ore. The vein is from 5 to 8 ft. wide, the ore shipping about one ounce gold per ton. The Iron vein strikes north, toward the Queen Bess, but has not yet been opened up that property.

Two sets of lessees, Frank Caley of Littleton, Colorado, and the Cripple Creek Deep Leasing Co., a Denver corporation, are operating the Jerry Johnson mine on Ironclad hill, and producing steadily. Five cars of two-ounce ore were sent from the Caley lease, and the Deep Leasing Co. shipped 10 cars of \$20 ore to the valley mills during July. The Caley lease extends to the 650-ft. level of the main Jerry Johnson shaft; the Cripple Creek Deep Leasing Co. is mining at the 850-ft. level.

The South Burns mine of the Acacia Gold Mining Co. has been closed down, while the plant is being overhauled and a new electric motor installed. The South Burns in July produced 9 cars of ore, 5 on company account and 4 by lessees, of an average value of \$23 per ton.

The Dig Gold Mining Co., M. B. Burke, of Denver, president and general manager, has installed a steam-hoist and 80-hp. boiler at its new shaft on the line between the Alpha and Omega claims on the south slope of Gold hill, and preparatory to sinking has laid an air-line to the compressor at the Hummer shaft, of the Gold Bond Consolidated Mines Co. adjoining. The company has ore at the 100-ft. level and will mine this ore when sinking. The Rubie or Worcester mill, on the Rubie property, on Bull hill, has been purchased by Thomas Kavanaugh, Ben Morrow, and Charles Bartell, and treatment

of low-grade dump-ores was resumed the first of the week. The mill is treating the dump-ore from the Rubie mine.

Dividends will be paid on August 10 by the Cresson Consolidated G. M. & M. Co. and the Golden Cycle M. & R. Co. The Cresson dividend is \$122,000 and that of the Golden Cycle, \$45,000. A. E. Carlton is president of both companies.

The Roosevelt Tunnel of the Cripple Creek Deep Drainage & Tunnel Co. was advanced 178 ft. with one shift in July; the lateral heading, toward the Cresson mine, was driven 100 ft. The flow from the portal raised last month to 5930 gal. per minute, due to the cutting of a water-course near to the east side-line of the Old Ironsides claim of the United Gold Mines Company.

### PLATTEVILLE, WISCONSIN

OUTPUT FOR JULY SHOWS DECREASE IN QUANTITY BUT INCREASE IN PROFITS.—ENTIRE ZINC-LEAD FIELD IS ACTIVE.—FIGURES OF PRODUCTION.—SEVERAL NEW ENTERPRISES.

The month of July, regarded as the banner month in the zinc-lead districts of Wisconsin, this year failed to uphold the tradition. Investigation revealed that it was due largely to enlistments. This, combined with the great unrest among the foreigners employed, told the story. One of the leading operators of the field, employing nearly 400 men, says that his company could use an additional 500, and that only one of the seven mines under his management was being operated with a full crew. Owing to lack of sufficient labor to operate on full time no further development will be undertaken until the labor situation improves. At the Graham mine, in the Galena district, the manager said negro miners had been employed and were proving satisfactory; that they were well behaved and labored diligently with good results. While the output of zinc ore diminished during July and while mine managers deplored the high cost of operating, it was found that it had been a successful period from the point of profit-taking.

While there came in mid-month a break in the price of zinc ore there was a uniformity of prices throughout the month that promoted business, the base price at the beginning of the month standing at \$75 per ton for standard and premium-grade ore, with the range down to \$70. These figures held steadily for the first two weeks, when with the softening in the price of spelter came a sympathetic downward movement in zinc-ore prices. Quotations for the third week ruled at \$70 base for premium and standard-grades, down to \$65 for the medium and second-grade ores, which held through the month, and as the demand for high-grade ore was constant, sales and shipments held fairly well above the base. The buying lacked the spectacular features that accompany competitive bidding, and business was steady and good. The lower-grade ores, and this includes all grades from 54% down, did not fare so well.

Discrimination in offerings was marked, and independent producers who were able to market their output congratulated themselves that they had a market. During the latter half of the month 45% was bid in at \$35, 40% at \$29, 35% at \$25, and 30% at \$20. Some ore was carried over by low-grade producers, and there were a few instances of shut-downs. Some claimed that ore producers were not receiving prices compatible with the metal market, but the larger operators said that makers of ordinary spelter have been paying all they could afford for zinc ore.

Lead-ore producers complained of their treatment during the month. The price for lead ore at the beginning of the month was \$120 per ton, base of 80% metal content, and some high-grade material was sold above this quotation. The trade in pig-lead was normal throughout the month and the price was less affected than was spelter. Regardless of this, and that quotations on futures were practically suspended, the price of lead ore came down to \$115 per ton about the middle

of the month to \$110 the last week of the month. Production showed appreciable gains, good weather enabling many small companies to work old mines and shallow diggings with little expense, and the shipment of mixed lots of ore was reported frequently. Two exclusive lead-ore producers were developed, the McDermott, in the Shullsburg district being one, and the Annex, in the Cuba City district, being the other. Both reported shipments of lead ore of high grade. Shipments for the entire month were higher than for many months past and would have been greater had high prices continued. The drop in price found lead-ore producers alert, and they promptly closed up on deliveries, only two cars leaving the field the last week of July. A conservative tabulation of lead ore held in bin in the several districts showed close to 1500 tons being carried over, and yet no one district could boast more than two or three cars at the most. The lead situation is better controlled than the zinc, being in fewer hands, and competition is being restricted.

The carbonate zinc-ore producing part of the field, at one time important in output, was idle except for the operations of the New Jersey Zinc Co. in both the Centerville and Highland districts. Scores of small companies, composed of local men, have discontinued mining activity. At no time within the past five years has there been a semblance of competition in the purchase of this class of zinc ore. Occasionally outside buying-agents have dared the opposition of the New Jersey Zinc Co., which controls these districts, owning and operating the only railway line, but in no instance have they tarried long, and miners have come to recognize their dependence on this one company and have accepted the situation, there being but one alternative, that of abandoning the mines. The New Jersey Zinc Co., on the other hand, is giving employment to all miners at several newly developed and equipped properties, and the district is as prosperous as it had been under the old order of things. More men are required than can be had, and the only drawback is lack of sufficient water for concentration. This is being overcome by boring deep wells, one of which, over 700 ft. deep, is now being supplied with pumps.

Shipments of pyrite for the month were confined to separating-plants exclusively and were lighter than usual. There has been no change in price, as the ore is all sold under contract to acid makers, and sellers refuse to divulge the price agreement.

The total deliveries of zinc ore, lead ore, and iron pyrite from mines to local refineries and to smelters direct, for the month of July, up to and including the 28th, were: zinc, 36,528,000 lb.; lead, 1,591,000 lb.; pyrite, 5,946,000 pounds.

High-grade ore from refining-plants shipped to smelters was reported as follows:

	Lb.
Mineral Point Zinc Co.....	5,256,000
National Separators .....	4,038,000
Benton Roasters and Wisconsin Zinc Co.....	2,732,000
Linden Zinc Co.....	320,000

Total .....12,346,000

The gross recovery from concentrators for July totaled 18,364 short tons; net deliveries out of the field both from mines to smelters and from reduction plants to smelters, 10,813 tons.

Sales and distribution of zinc ores were made as here shown to the buying companies represented in the field. Mineral Point Zinc Co., 5676 tons; Grasselli Chemical Co., 2514 tons; National Separators, 3573 tons; Wisconsin Zinc Roasters, 3024 tons; American Zinc Co., Hillsboro, Illinois, 1809 tons; Linden Zinc Co., 1360 tons; M. & H. Zinc Co., La Salle, 649 tons; Illinois Zinc Co., 630 tons; Benton Roasters, 462 tons; Lanyon Zinc Co., 355 tons; American Metal Co., 313 tons; Edgar Zinc Co., 280 tons; Sandoval Zinc Co., 35 tons. A total of 20,526 tons.

# THE MINING SUMMARY

*The news of the week as told by our special correspondents and compiled from the local press.*

## ALASKA

(Special Correspondence.)—W. A. Dickey, who has been opening up and preparing to operate the old Barrack property, owned by the Latouche Copper Mines Co., and adjoining Beatson's Bonanza, of the Kennecott company, has shipped on the steamer 'Cordova' 300 tons of ore to the Tacoma smelter. This ore is hand-sorted and it is expected to run between 5 and 6% copper. This property made two previous shipments several years ago, one of 800 tons to Tacoma smelter, and one of 250 tons to Ladysmith, the returns from neither being satisfactory to the owners at the price of copper at that time. It is now claimed by the management that a sufficient tonnage is blocked out to assure them a place among regular shippers.

Latouche, July 31.

(Special Correspondence.)—The Ellamar mine, at Virginia Bay, is now shipping from 5000 to 6000 tons per month to the Tacoma smelter. This ore is low in copper, 2% or under, but carries from \$3 to \$5 gold per ton, and is a much desired ore at Tacoma on account of its iron content. Eighty men are employed. The mine is under the management of L. L. Middlecamp for the Ellamar Mining Company.

Ellamar, July 30.

(Special Correspondence.)—The Midas mine, of the Granby company, across the bay from Valdez, is producing 200 tons of ore per day, which is shipped to the company's smelter at Anyox, B. C. This mine employs 75 men, and is under the management of Palmer Cook.

Valdez, July 31.

## ARIZONA

### COCHISE COUNTY

(Special Correspondence.)—Since the taking over of the Mascot Copper property by the American Smelting & Refining Co. it is estimated that shipments for the month of July will reach 2500 tons. Report says that preparations are being made to take on a large force of miners.

Dos Cabezas, August 2.

### GILA COUNTY

At Globe, after an idleness of five weeks, the smelter of the Old Dominion company was again blown-in on August 8. The concentrator also was started during the week, though both smelter and concentrator will not be operated at full capacity. The workmen, whose number is increasing daily, go to and from work under armed guards, so no disturbances occurred, though 300 union pickets lined the main street leading to the works. Of all the men accepted not a single I. W. W. was included.

### PIMA COUNTY

(Special Correspondence.)—A new wulfenite property has been opened up by the Vail interests on one of the claims of the old Total Wreck mining property, 9 miles south of Pantano station.

The owners are sinking and taking out about a carload of 34 ore weekly, using a gas-hoist. The ore is sacked and shipped to Tucson, where it is concentrated.

Wulfenite was known here 30 years ago, but at that time the Total Wreck was a silver-lead property, and as the wulfenite then had no value it was thrown on the dump, which dump has lately been worked over. Work was begun six months ago, under the direction of E. L. Vail, who employs 25 men.

This property has been a big producer of high-grade silver ore, and 30 years ago was equipped with a 20-stamp mill and 250-hp. Corliss engine.

The Arizona Rare Metals Co., under the management of R. O. Boykin, has erected a leaching and concentrating plant in Tucson to recover the sodium molybdate from the slag obtained in smelting.

The slag is ground in a ball-mill and is then run into filter-tanks. The filtrate is placed in evaporating pans and the sodium molybdate recovered from the solution.

The concentration plant was added for the treatment of wulfenite, and is handling all the output of the Total Wreck mine. The ore is fed to a crusher, elevated to shaking-screens, and the oversize passed through rolls. It then passes over a Wilfley table. The mill has a capacity of 5 tons per 8 hours.

Tucson, August 5.

(Special Correspondence.)—A strike of copper-zinc-lead-silver ore is reported by Edward G. Bush, manager on the 200-ft. level of the San Xavier Extension Copper Co.'s mine in the Twin Buttes mining district. A sample taken across the face shows silver, 32.8 oz., copper 6.34, lead 12.5, and zinc 23.5. This vein was struck on the 140-ft. level, where it assayed 50% zinc, 1% copper, 8% lead, and 4 oz. silver. The drift has been run for 25 ft. on the ore. The San Xavier Extension touches the Vulcan mine on one end and the Wakefield on the other. The vein shows also on the Wakefield claim.

It is understood that a deal is pending on the Wakefield property, which now adjoins operating companies on three sides.

Ben Heney has negotiated a deal with E. D. Sullivan on the Pandora and Fairbanks claims in the Twin Buttes district. Negotiations on three other groups controlled by Alex Rossi in this district are now pending. It is understood that Mr. Heney has interested Idaho capitalists who looked the property over in the early part of July.

Walter Harvey Weed, consulting engineer for the Magnet Copper Co., was in Tucson last week, and said that he had been asked to make a report on the conditions in Twin Buttes district with a view to the erection of a smelter.

He said that the first drill-hole on the Magnet property had verified his opinion of the existence of ore similar to that in the large porphyry mines of this country. The bore-hole proved the ore to be of low copper content at water-level 80 ft. below the surface. At 160 ft. down, the value had gradually increased till 5 ft. of 6% copper ore was pierced. From all the assay returns of the bore-hole samples it is estimated that there is 60 ft. of ore averaging 2.08% copper. The extent of this orebody has to be proved by more drilling, and there is reason to believe that results as good as were obtained in hole No. 1 will be duplicated in the other holes which are now being bored. Development work will be continued, being directed by the results obtained by drilling.

Twin Buttes, August 3.

### PINAL COUNTY

(Special Correspondence.)—The 10-hp. hoist recently bought by the Magmatic Copper Co. has been installed, and it is now expected to make better progress in shaft sinking. When the hoist was put in, the shaft was down 112 ft. The shaft is still in a grade of manganese ore, which it is believed will meet the market requirements.

Florence, August 2.

## SANTA CRUZ COUNTY

(Special Correspondence.)—J. Smith and two companions, of Warren, Pennsylvania, who are said to be the principal owners of the Mowry mine, were in the district last week and have made arrangements again to work the old mine. It is announced that a concentrator will be built and a new shaft sunk, the work to be started within 30 days. It is thought that this decision of the Pennsylvania capitalists and the announcement that they intend to work the property ends the deal that has been pending for some time with the Standard Metals Co. of Los Angeles for the sale of the property.

Patagonia, August 3.

## YAVAPAI COUNTY

(Special Correspondence.)—Louis Goldman, the president of the Copper Queen Gold Mining Co., has made an inspection of the company's property in this county, 6 miles east of Humboldt. The mine is now in condition to produce 100 tons of ore per day. The output will be treated at the Binghamton plant and delivery commenced in a short time.

Some interest is being caused by the revival of the report that there are possibilities for oil in the Big Chino valley. To date 100,000 acres of land has been leased, and it is reported drilling-rigs are coming in.

Prescott, August 3.

## YUMA COUNTY

(Special Correspondence.)—The Billie Mack Co. is shipping a 40-ton car of ore to the A. S. & R. Co. at Hayden this week, and another car is in the course of preparation from the older workings on the property, formerly known as the Ruby. The ores are chrysocolla and malachite. Development work is being done on what is known as the Jay Bee vein. Jackhammers are being used. W. Dowe, of Chicago, general manager for the company, will soon be on the ground when extensive plans will be made for further development of Lion hill. The advent of cooler weather will see greater activity in this district.

Parker, August 6.

## CALIFORNIA

The number of new oil-wells reported to the State Mining Bureau during the week ended August 4, was six. Only once during the present year has such a low number been reported, the total to date being 673. There is as yet no definite indication of a widespread slackening of development which may be expected from a shortage of casing and other materials. The starting of a well in the Newhall field, which is one of the oldest in the State, is of almost as much interest as the fact that the Midway-Sunset fields started only three wells. The number of wells in the course of drilling and ready for test of water shut-off is 22, which is near the normal number. Wells being deepened or re-drilled, as a means to maintaining or increasing productiveness, number 15, which is also about the usual number. This week the number of wells abandoned is 5, making a total of 211 for the year.

The Bureau is engaged in formulating rules for the abandonment of wells. Before the rules are finally adopted the opinions and criticism of operators will be sought. A draft of the proposed rules may now be obtained at the local offices of the Bureau.

## BUTTE COUNTY

(Special Correspondence.)—The Union Crome Co., of San Francisco, has been working several chrome deposits in this neighborhood, and shipping ore of very good grade. One deposit is near Concow, another on the Curtis ranch near Paradise, and another on Little Butte creek. The Butte creek property is working eight men. J. Davis is superintendent.

The Springer mine, near De Sabla, is working 25 men. John Kirchen, of Reno, Nevada, is the owner, and Harry Thompson is superintendent. This is a large quartz property and has

been rich enough in the past to work by ground-sluice and placer methods for the pockets it contained. The present method is to work the entire vein on a large scale. The crushing, concentrating, grinding, and cyaniding plant is complete. This is the largest property working in this district.

The Mineral Slide Mining Co., controlled by Moody and Cohn, is under option to J. C. Cowan and associates of Salt Lake City, who have been working 24 men. Machine-drills have been installed, also a screen washing-plant. Some good ground has been opened up and it is likely that this property will be good for a number of years. Considerable money has been spent in development and equipment and it is thought that the option will be exercised. The property is shut-down this month due to trouble over water rights but is expected to resume operations in about two weeks. This property is on Little Butte creek, and adjoins the Lucky John mine on the west.

The Blue Hog drift mine near Magalia, is working six men. Los Angeles people are the owners.

The Kirby drift mine also is working. Seven men are employed. This property is near De Sabla. J. C. Kirby is the owner. A new shaft is being sunk.

The Paradise irrigation district is rushing work on the dam on Butte creek above Magalia, and also on the ditch system. Modern engineering methods are used and a ditching-machine is digging the main ditch. This system will supply water to an extensive district, for irrigation and domestic purposes.

It is to be regretted that here again the farming and mining interests clash, as the laws do not allow water to be sold for mining purposes. Some mining land, absolutely useless for farming, was included in this district, and the owners have the privilege of paying taxes on the improvement without being allowed to have the water.

Prospectors are active in this district, looking for chrome, manganese, cinabar, and other ores. It is possible that this activity will result in the discovery of some deposits of value.

Paradise, August 7.

## DEL NORTE COUNTY

(Special Correspondence.)—E. P. Moore, of Berkeley, who is managing chrome mines in the Low Divide district, has 3000 tons ready to ship. In one place two men are breaking 50 tons daily. The 88 tons of chrome, which was on the steamer 'Del Norte' when it was beached, was from this property.

George Hyde has located 15 chrome claims on a line between Low Divide and the north fork of Smith river.

Crescent City, August 8.

## INYO COUNTY

(Special Correspondence.)—The Round Valley Tungsten Co. began the use of electric power July 31, when the mill was started up. An innovation has been introduced here in the form of a ball-mill for grinding—replacing rolls. The result of this radical change is being watched with great interest by the managers of the other tungsten mines of the district, for if the experiment should prove satisfactory others will put in ball-mills. Mr. Shapley is manager for the Round Valley company.

The Standard Tungsten company has bought a Marcy ball-mill, and a new flow-sheet is being worked out. Preparations are being made for the new machinery, which is expected to arrive within 30 days. The mill will be increased to 150 tons daily capacity. L. E. Porter is general superintendent and H. R. Potter is mill superintendent.

Bishop, August 3.

## NEVADA COUNTY

(Special Correspondence.)—The 20-stamp mill at the Allison Ranch is running on good ore from the 400-ft. level. The mine has been opened to an approximate depth of 625 ft., and four stopes are being worked. Unwatering of the lower levels

continues, and deep mining will begin in the early fall. C. K. Brockington is general manager.

Walter W. Bryne, representing Salt Lake capital, has completed arrangements for work at the Franklin and Ford properties, adjoining the Allison Ranch. Orders have been placed for an electric pump, a 75-hp. hoist, and a 10-drill compressor. Old records show that when last operated the mines produced ore averaging around \$160 per ton.

The North Star Mines Co. has completed raising of the county road 10 to 12 ft., forming a dam around the cyanide plant, for the impounding of tailing and calculated to have a capacity for at least two years. Extensive work continues in the lower workings of the Central mine, and the Central mill is running at full capacity. The company is reported to be considering the acquisition of new holdings.

In the Rough and Ready district, controlled by King C. Gillett and associates of Los Angeles, work has been temporarily suspended at the California. New machinery has been installed and much development work done. It is stated work will be resumed when cost of materials is lower.

Work has begun at the Delhi mine, above Nevada City, recently taken under lease and option by A. A. Codd, of Reno, Nevada. The boarding-house, bunk-house, office-building, and other structures are being moved to near the portal of the lower adit.

Grass Valley, August 12.

#### PLUMAS COUNTY

(Special Correspondence.)—The Robinson mine, in Granite basin, has passed from the United States Exploration Co. to a new company—the Golden Feather Mines Co. The stock is now assessable and the first assessment has been levied and work will be resumed. There is stated to be a good shoot of ore on the 80-ft. level. On the 320-ft. level the ore-shoot was not found where expected and driving was done, which resulted in finding what is thought to be the north end of the shoot. The vein at that place was 10 in. wide and assays \$27. Further development will be done.

Oroville, August 8.

#### SHASTA COUNTY

(Special Correspondence.)—Construction of a five-mile flume has been started by the Victor Power & Development Co. to supply power to the Midas mine and mill, near Knob. It will connect with a five-mile ditch from Brown's creek. Two Bessemer gas-engines have been installed to operate the generating plant during the time when water is not available. Unwatering of the shaft by bailing is proceeding and at about 600 ft. the pumps will be recovered and started. Improvements will also be made in the mill, and development of the Gold Hill mine will proceed from the Midas shaft.

It is reported that the Arnstein interests, now operating the Bully Hill group, near Copper City, have decided to build a flotation plant, of which the first 100-ton unit is to be erected before winter. The company is shipping 50 tons of ore daily to the Mammoth smelter, and has started work from the Rising Star shaft. L. C. Monahan is superintendent.

The 150-ton flotation plant of the Afterthought Copper Co. will be given a trial about September 1. Completion of the plant has been delayed by slow shipment of material from the East, but all equipment is now in place. Mine operations are being increased and the bins are filled with ore.

The Shasta Belmont Co. has arranged for the extension of the lower adit and for the driving of a cross-cut to open a small rich vein. There is some good ore in the old adit-level and the management is contemplating shipments. The mine lies near the Bully Hill and Arps properties, and the ore is noted for a high silver content in addition to good copper average, besides zinc and gold. W. E. Casson, of Carson City, Nevada, is manager.

In the French Gulch district the Sybil is being worked by

the Shasta Hills company, and arrangements have been made for the development of the Black Tom. Prospecting is active.

Redding, August 7.

### COLORADO

During the calendar year 1916, Colorado produced \$19,148,320 in gold, 7,622,000 oz. silver, 70,358,000 lb. of lead-bullion, and leaded zinc oxide, 8,940,000 lb. of copper and 129,300,000 lb. of zinc in spelter and oxide. The total value of the production was \$48,550,318.

#### BOULDER COUNTY

(Special Correspondence.)—Around Ward the busy mining season has commenced. The big mines of the district are free from the snow that closes many of them each winter. Ore shipments are increasing. On the Texas, work has been started. C. J. Walter is in charge.

The National Tungsten Co. will complete its mill this month. The property has been a steady producer. T. E. McKinney, manager of the Lula B. properties, has arrived from New York and will make extensive improvements. The Oronogo machinery and shaft-house has been moved to the Snowbound, on Gold hill. Fred Gushe will be in charge. The Big 5 is putting in a ball-mill and making other improvements. The Boulder Natural Gas Co. has incorporated and will operate in Boulder county. O. R. Whitaker, of Denver, has been appointed to investigate the smelter-trust on behalf of Colorado miners. The Consolidated Leasing Co., of which C. E. Kahler, of Columbus, Ohio, is president, is at work. When Mr. Kahler returns, work will be started on the mill. The Boulder Tungsten Production Co.'s refinery is said to be the largest and most complete tungsten-mill in America. Tungsten ores are coming here from other States, for treatment, and all the mines and mills in this district are preparing to ship ore here for treatment. The National Tungsten Co. has been overhauling its mill, which is now in good condition.

The Smelter and Ore-Sales Committee, of Boulder, is making good progress and will soon have its report ready for the public.

Eldora, August 4.

#### ROUTT COUNTY

(Special Correspondence.)—The Routt county oil-shale deposits will probably add another industry to the productive resources of this county. Thos. J. Williams, and several others, have organized the Tow Creek Oil & Asphalt Refining Co. The company has taken an option on 2500 acres of land, upon which other minerals than oil-shales have been found, including an 8-ft. vein of paraffine. Fire-clay of high grade has also been opened.

Eldora, July 28.

#### TELLER COUNTY

(Special Correspondence.)—Machinery has been placed and necessary arrangements have been made to sink the shaft of the Wild Horse mine, at Midway, the purpose of which is to explore undeveloped territory. The work is being done on company account by the United Gold Mines Co., J. J. Russell, superintendent. The ore of the Cresson Consolidated mine has a value of \$500 per ton without sorting.

The new Portland custom mill at Victor is about completed. It will have an initial capacity of 1500 tons.

Ben Baud of Victor has a contract to sink 400 ft. in the Rose Nichol shaft at Victor. In the Longfellow, Mr. Southerland has cut a station at 350 ft. and has a contract to sink an additional 250 feet.

Edwin Gaylord, lessee of the Forest Queen, is installing two new boilers, and expects to produce a carload of ore daily.

It is reported that Tom Kavanaugh has taken over the Worcester mill and lease on the Ruby mine and will treat the ore from the La Fayette dump.

Lessees on the Little May, on Bull Cliffs, has opened up ore on this long neglected property.

Dick Curry has secured a lease on the Star of Bethlehem mine at Independence, and is sinking a new shaft.

Victor, August 2.

## MONTANA

### JEFFERSON COUNTY

(Special Correspondence.)—A 14-ft. orebody is being mined at the Mt. Washington mine near Wickes. The ore is lead-silver and is worth \$35 per ton. The strike was made in an adit about 3000 ft. from the portal and 700 ft. below the surface. The stope is three sets wide. The Mt. Washington is controlled by Duluth, Minnesota, interests.

The Gregory slag dump, which has remained undisturbed for more than 30 years, is being hauled in wagons to the railroad at Wickes and shipped to the smelter. The slag carries silver and lead. The ores were smelted with charcoal. Recoveries from the slag shipped average near \$20 per ton.

Alta Mountain, at Crobin, which has produced from the Alta mines \$32,000,000, is the scene of much activity. The Boston & Corbin company is mining and milling a large tonnage of copper ore. The Alta Mines Co. is developing the old Alta property and a new discovery has been made of silver-lead ore. The strike was made in a blind vein and is 6 ft. wide. The Butte & Corbin property is also producing shipping ore.

At Clancy a new corporation has been formed to work the Dan Tucker mine. New machinery has been installed and work is progressing.

Clancy, August 2.

### LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Marysville district is mining and milling more ore than for many years. The Barnes-King company is working the Shannon, a new property; also the old Piegan-Gloster group. The St. Louis company is operating the Drumlummon mine. Ore is being drawn from the old stopes and is run through a 25-stamp electric-driven mill with cyanide plant having a capacity of 100 tons per day. Lessees are mining ore from a claim producing lead-silver ore at Bald Butte, and a new compressor is being sought by the Bald Butte Co. The Nile mine in Towsley gulch is shipping. Marysville, August 3.

## NEVADA

### ESMERALDA COUNTY

(Special Correspondence.)—The Goldfield Consolidated has purchased the Sure-ease gold mine, in the Big Bend district, near Oroville, from Phebe Bros., of Oakland, California. Work has begun under the management of Robert J. Burgess. Ore of good grade is said to be exposed. The Goldfield Consolidated is also negotiating for other mines in California. In an area recently leased from the Jumbo Extension Co., the Consolidated has opened a deposit of rich ore and is sending it to the cyanide-section of the mill. From the 450-M winze on the 600-ft. level of the Laguna, flotation-ore assaying \$133 per ton is being produced. There is still difficulty in marketing of flotation concentrate, due to congestion at the custom smelters. It is reported the company is considering improvements in its refining-plant for treatment of the flotation concentrate, to be followed by placing of the second flotation-unit in operation on ore from the Atlanta, Kewanas, and other mines.

The Atlanta company has announced that the winze from the 1750-ft. level will be enlarged and sunk to 2000 ft. to open a copper-gold vein and to determine whether or not the orebodies persist beyond the shale. The company is making regular and profitable shipments to the sampler of the Western Ore Purchasing Company.

The Western Ore Purchasing Co. has filed suit for \$9143 against the Florence Goldfield Co. alleging this amount was secured from plaintiff through defendant having salted an ore shipment. The complaint recites that 37 dry tons of ore was

purchased by plaintiff on fraudulent samples submitted by the Florence Goldfield Co., indicating the shipment to be worth \$9226, but that when reduced the total value of ore was found to be only \$83.11.

The winze from the north drift on the 880-ft. level of the Jumbo Junior has exposed ore assaying around \$100 per ton in the area leased from the Kewanas company. A raise at this point also shows good ore. A shipment will be made. The Kewanas company has started cross-cutting near this point and is exposing seams of rich ore, in which gold predominates, with a little copper showing.

Goldfield, August 14.

### NYE COUNTY

(Special Correspondence.)—An interruption in the power-service the past week, suspended station work on the 1680-ft. level of the Victor, and dewatering the shaft has superseded the station work. The development at the Tonopah Extension consisted of 55 ft. in No. 2 shaft, and 114 ft. in the Victor, on the 1440 and 1540-ft. levels. Stopping on the 1260-ft. level of the No. 2 shaft continues on the Murray vein, which shows 8 ft. of ore; also on the O. K. and Merger veins, each of which has a 6-ft. face of ore. The past week 2380 tons of ore was sent to the mill.

The Rescue-Eula sent 188 tons to the West End mill the past week from the 950 and 1050-ft. levels.

The Tonopah Belmont sent 2744 tons of ore to the mill the past week. On the 8th level the east drift on the Rhyolite vein is in fair ore 2 ft. wide. A cross-cut has been started between the 8th and 9th levels in the hanging wall of the Belmont vein, toward the extension of the Shaft vein. On the 9th level west on the Rescue vein, there is 3 ft. of vein material. The Shoestring vein at present averages 2 ft. of fair ore.

The clean-up of the West End for the last half of July consisted of 33 bars valued at \$54,000. Development in the Ohio shaft is progressing, and the West End shaft continues to supply its usual tonnage. The Halifax Tonopah has resumed stoping.

The development work of the Tonopah Mining Co. the past week consisted of 88 ft. in the Silver Top, and 35 ft. in the Sandgrass. The raise from the 540-ft. level of the Silver Top intersected the West End-McNamara vein, which shows 2 ft. of a good grade of ore. The new stope on the 1150-ft. level on the upper Sandgrass vein shows ore of fair value, and 1800 tons was sent to the mill the past week.

Tonopah, August 6.

## NEW MEXICO

### GRANT COUNTY

(Special Correspondence.)—All of the new Phelps-Dodge buildings at Tyrone are completed. The situation which these buildings occupy has been named the New Town, and is one mile from where the Tyrone post-office was situated. The six Phelps-Dodge buildings are an up-to-date general store, and warehouse, the general office of the Burro Mountain branch, the high school, the freight warehouse, and a beautiful little station and post-office combined. All of these buildings are of stucco work, in the Spanish style, and the stucco of each building is tinted a different hue.

During June the No. 1 and 2 divisions of the mill produced 44,199 tons of ore averaging 1.9% copper. The average daily production was 1542 wet tons.

The corporation is installing two new General Electric storage-battery locomotives, Type LSB. Each motor has a rated speed of 4 miles per hour at full load. The power is furnished by a battery of 63 Edison cells at 60 volts potential. These locomotives will operate on a 20-in. gauge track. Three batteries are used in the haulage system, one of the batteries, fully charged, being kept in spare. Thus, when the battery on

one of the locomotives has been run down, the locomotives will be driven to the charging-station where the engineer will replace the run-down battery with the spare and the former will be recharged and in its turn become the spare. Both locomotives will operate in the No. 3 division.

Tyrone, July 27.

#### SOCORRO COUNTY

(Special Correspondence).—The tonnage for the Mogollon district during July amounted to approximately 12,000 tons, which yielded nearly 6000 lb. of gold and silver.

The first installment for a diamond-drill has arrived at the Mogollon mines.

The Oaks Co. continues to ship daily from the Maud S. mine. The property had not been worked for years, but the conditions found by the new operators seem to be satisfactory.

Mogollon, July 31.

#### OREGON

##### JACKSON COUNTY

(Special Correspondence).—W. P. Chisholm of the Mercur and Little Jean claims, 12 miles north of Gold Hill, is installing a 12-pipe Johnson and McKay furnace on his property. The machinery is from the Joshua Hendy Iron Works, San Francisco. The claims are in a wooded district, and plenty of water is available. It will be in operation in less than 30 days. R. H. Spencer and associates, of Portland, who recently acquired the 73 group of quicksilver mines near the Chisholm group has a 3-pipe Johnson and McKay furnace, which is operating successfully. They will add 9 retorts as soon as they can be had. Other owners have ordered the same furnace, to be installed as soon as possible.

The Red Hill gold quartz mine, in the Jump-off Joe district, five miles east of the Greenback mine, and three miles from Three Pines station on the Southern Pacific railway, is being re-opened. It is owned by T. N. Anderson of Gold Hill, and Lester Lord of Danberry, Nebraska. The property was originally discovered and operated by Joseph Dysert, who mined a large amount of rich ore, which he reduced with an arrastra. The vein is at contact of red porphyry and serpentine. The main drift, in 500 ft. on the vein, is being re-timbered, and ore shipments will be made. The power-line of the C. & O. Power Co. crosses the premises.

Samuel Carpenter and Harry Hocksworth, of Medford, are shipping antimony ore regularly to New Jersey from their Applegate mine. The ore is running 50% antimony with some gold. This property is 17 miles south-west of Jacksonville. The vein is from 18 in. to 4 ft. wide, with 400 ft. of drift.

The United Copper Co. has struck ore on its property that runs 35% copper. These mines are in the Greenback district in the north-west part of Jackson county at the head of Slate creek. The ore deposit is in a fissure in andesite. The development made last season exposed in surface cuts a vein which runs 5% copper and \$2 gold. The company operates a mill and concentrates the sulphides, which are shipped. The plant is being enlarged. The company is constructing a road from the mine to Evans Creek valley leading to Rogue river, 9 miles west of Gold Hill.

E. H. Richards and A. W. Bartlett, of Grants Pass, recently leased from M. G. Womack, of Medford, and M. A. Carter, of Ashland, a vein of molybdenite near Jacksonville. The lessees are developing the prospect.

Gold Hill, August 6.

##### JOSEPHINE COUNTY

(Special Correspondence).—More chrome deposits have been located in Fiddlers gulch, six miles west of Kerby, by Fred Hart and T. P. Johnson. Dave Bauer and J. W. Bigelow also are developing chrome down the Illinois river.

The Neils Success gold mine is in operation under the management of R. J. Firth, of Seattle.

Kerby, August 8.

## Personal

*Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.*

B. L. THANE is at Seattle.

W. L. HONNOLD is at Los Angeles.

F. H. MITCHELL has returned to Nevada.

WILLIAM B. FISHER is at Salt Lake City.

D. M. RIORDAN has returned from New York.

A. B. ROGERS was here, from Los Angeles, last week.

JOHN C. RHOADS is in Shasta county, at Copper City.

H. F. SCHEERER is in San Francisco from Tucson, Arizona.

M. B. YUNG sails by the 'Korea' on August 22 for Hongkong.

ROBERT E. CRANSTON has gone to Colorado, to return in two weeks.

RENSSELAER TOLL will be at Kingman, Arizona, until August 20.

DON C. BILLOCK has returned to Berkeley from Latouche, Alaska.

SCOTT TURNER is at Lima, Peru, on his return from La Paz, Bolivia.

W. W. DEGGE has returned to Boulder county, Colorado, from the East.

EUGENE C. SNEDAKER has received a commission in the Engineer Corps.

R. H. CLARKE is chemist with the Chino Copper Co., at Hurley, New Mexico.

HORACE V. WINCHELL sailed from Yokohama on August 24 on his return from China.

WALTER G. PERKINS has returned from visits to Garfield, Utah, and Hayden, Arizona.

CHESTER A. THOMAS, manager for the Yukon Gold Co., was in San Francisco last week.

A. F. HALLETT has been appointed chemist to the Khirgiz Mining Co., at Ekibastus, in Siberia.

MANUEL EISSLER, the author of many metallurgical textbooks, is here, on his return from China.

H. R. BOSTWICK is in Japan. He does not expect to return to San Francisco until early in November.

HERBERT C. ENOS is at Chihuahua, Mexico, in charge of properties for the Compania de Minerales y Metales.

C. B. CLYNE has been engaged to design and build a flotation plant for the Demming Mines Co., at Murphy, Idaho.

LIVINGSTON WERNECKE, geologist for the Treadwell company, has gone to Wrangal to examine mines in that vicinity.

TATSURO OTAGAWA has been transferred from the Kyoto Imperial University to the Northwestern Imperial University of Japan.

ORVIL R. WHITAKER has been appointed to take charge of the technical part of the official smelter and ore-sales investigation now being made in Colorado.

CHARLES R. FETKE is engaged in making a geological survey of Clay and Macon counties, Tennessee, with reference to the possible occurrence of oil and gas.

ROBERT T. HILL has opened an office at 702 Hollingsworth Bldg., Los Angeles, having completed his report upon the geology of southern California for the U. S. Geological Survey.

GEORGE H. CLEVINGER and WILLIAM G. RAYMOND have declined the presidency of the Colorado School of Mines. Another candidate is ORVILLE HARRINGTON, editor of the School magazine.

# THE METAL MARKET

## METAL PRICES

San Francisco, August 14

Aluminum-dust (100-lb. lots), per lb.	\$1.00
Aluminum-dust (ton lots), per lb.	\$0.95
Antimony, cents per pound.	15.50-18.00
Electrolytic copper, cents per pound.	29.50
Pig lead, cents per pound.	12.25-12.50
Platinum, soft and hard metal, per ounce.	\$105-111
Quicksilver, per flask of 75 lb.	\$115
Spelter, cents per pound.	10.75
Tin, cents per pound.	60
Zinc-dust, cents per pound.	20

## ORE PRICES

San Francisco, August 14

Antimony, 50% metal, per unit.	\$1.20
Chrome, 40% and over, f.o.b. cars California, per unit.	\$0.60-0.70
Magnetite, crude, per ton.	\$8.00-10.00
Tungsten, 60% WO <sub>3</sub> , per unit.	26.00-30.00
Molybdenite, per unit for MoS <sub>2</sub> contained.	\$40.00-45.00
Manganese, 45% (under 35% metal not desired), cents, unit.	33-37

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese.	Per unit \$1.00
46 to 49% metallic manganese.	0.98
43 to 46% metallic manganese.	0.95
40 to 43% metallic manganese.	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

Chrome prices are causing considerable comment among both buyers and consumers. A San Francisco buyer quotes today the following schedule of prices:

35 to 37% .....	50c. per unit
37 to 40% .....	55c. " "
40 to 44% .....	60c. " "
44 to 48% .....	65c. " "
48% and over .....	70c. " "

These quotations are f.o.b. California and Oregon main-line railroad points. A certificate of sampling and analysis by a reliable chemist must be attached to bill of lading.

## EASTERN METAL MARKET

(By wire from New York)

August 14.—Copper is dull and quotations are nominal at 27.50 to 27c. Lead is lifeless, price 10.87 throughout the past week. Zinc has stood at 8.75c. all week. Platinum remains unchanged at \$105 for soft metal and \$111 for hard.

## TIN

Prices in New York, in cents per pound.

Dec.	55.34	76.70	...

Silver is quoted today in New York at 83.75c. per oz., a higher price than at any time since 1892, when it was at 87 cents.

A new ruling has been made by the Treasury Department regarding the purchase of gold-silver bullion. Heretofore the mints bought gold-silver bullion on the basis of the fineness in gold and silver, no matter what the ratio of gold to silver might be, provided the bullion contained at least 20% of the precious metals, that is, 200 fine. The Government assay offices, however, did not buy gold-silver bullion unless the bullion not

only was 200 fine but that the value of the gold contained was at least ten times as great as the silver in the bullion. This restriction has now been removed, according to a press dispatch—no official notification of the order having been received at the San Francisco Mint up to August 14. The Government assay offices may, therefore, accept and pay for any bullion containing gold and silver, if the amount of the precious metals constitutes at least 20% of the weight of the bullion offered.

## ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Dec.	16.75	11.26	...

The United States Geological Survey, from returns representing 99% of the output, estimates that the production of spelter during the first six months of 1917 was 354,000 short tons, as compared with 351,000 short tons during the last half of 1916. Stocks on hand are estimated at 33,000 tons, as compared with 17,600 at the beginning of the year. A large number of reports, about 35,000, including 14 complete plants, were reported idle June 30, in addition to the reports engaged in refining prime Western metal and in re-distilling zinc ashes.

## ORES

Tungsten: Asking prices are as high as \$23 per unit for 60% concentrates, with \$25 to \$26 quoted for some grades. Imports have been larger than expected, or 3823 gross tons for the 12 months ended June 30, 1917. Ferro-tungsten is quoted at \$2.25 to \$2.50 per lb. of contained tungsten, with both domestic and foreign demand excellent.

Molybdenum and antimony: Molybdenum is quoted unchanged at \$2.10 to \$2.20 per lb. of MoS<sub>2</sub> in 90% material with offerings readily absorbed. Antimony ore has sold at \$2.25 per unit for high-grade material.

# Eastern Metal Market

New York, August 8

The entire metal market is inactive and slow with prices practically nominal in almost every case. Government uncertainties as to purchases and prices continues to halt the trade and to act as a depressing influence. The whole trade is nearly demoralized.

Copper is lower but firm

Iron is quiet but steady

Lead is dull and almost nominal

Zinc is stagnant and unchanged

Antimony continues inactive

Aluminum is quiet at unchanged prices

The steel market continues upset by prospective price fixing and cost finding endeavors. Repeated outcries from Washington of sweeping action intended in the Government's dealings with steel makers and the suggestion of the President's call for a monopolistic policy have only added to the uncertainty that is holding back all iron and steel markets. Price changes in the north have been erratic. Buying for the Allies to hold up by the steel cost liquidity and make time for the latter will be necessary than was expected. Pig iron output in July fell off further due to coke shortage, heat and humidity. The decrease from June was 1200 tons per day, the same as the June decline from May.

## COPPER

The features of the copper market are the strong fundamental conditions and the continued dullness two elements not usually associated. Were it not for uncertainties at Washington business would probably be of larger proportions for certainly the demand is latent somewhere. With the amount of approximately 100,000 lb. of more bought by the Allies for delivery to July 1, 1917, practically all of which has been shipped and with the confident prospect of more copper needed from that quarter, it is not surprising at this country's needs, the future of the market is generally regarded as bright. But no one is willing to advance to the point where the price situation is where it is known as to what the Government will do continuously they are the latest one rising to \$22.25 per lb. No one knows and perhaps that will be known until the cost in transportation is completed which will be at least two or three weeks yet. The market is a poor and nominal one and has gradually weakened again. The last week saw considerable both local and overseas, more than 100,000 lb. of New York. Because of the uncertainty of which was the main reason for the market's advance that week. Before, however, the August 10th of which were mentioned. Before it came to pass, it was the fact that the market was in a position to be moved to some extent. A comparison made in the market was that the export of copper for June was 15,000 tons as compared with 10,000 tons for the same month in 1916. The market was in a position to be moved to some extent. A comparison made in the market was that the export of copper for June was 15,000 tons as compared with 10,000 tons for the same month in 1916. The market was in a position to be moved to some extent.

## IRON

The market is inactive and slow with prices practically nominal in almost every case. Government uncertainties as to purchases and prices continues to halt the trade and to act as a depressing influence. The whole trade is nearly demoralized.

The market was quiet on the surface, though one seller reported the disposition of 100 tons of futures, but no other sales were noted, and spot Straits was nominal. The principal activity this week has been in shipments from the East. Arrivals up to August 7 were 510 tons, but the quantity abroad has not been officially reported so far this month and it would not be surprising if this information is to be kept from the public, although no announcement to that effect has been made. The quotation yesterday was 63.62½¢, New York, for spot Straits. Yesterday the London quotation for spot Straits was £247, a decline of £1 from that of a week ago.

## LEAD

Whether the Government has really placed its order for 8000 tons of lead to cover its August requirements is not known, but many believe that this quantity has been bought at 8¢ per lb. as in the July purchase, but that no announcement will be made. The Government's needs dominate the entire future of this market. If they are to continue at 8000 tons per month, they will be sufficient to take up the ordinary stock in the market and absorb about one-quarter of the country's yearly output. A strong market is looked for with production keeping up at full pace. The extent to which transportation and labor troubles may hinder output in the future is a possible important factor. The market the past week has been quiet but firm and almost nominal at 10.87¢, New York, and 10.75¢, St. Louis. Labor troubles, which were prominent last week seem to have been settled in many cases. The leading interest still quotes 11¢, New York but sales have been made below this and we therefore quote the market at 10.87¢, New York. For the present the demand is small.

## ZINC

Surprise has been general in the trade the last week over the unexpected action of the Government as represented by the Zinc Committee in asking for bids on 11,500,000 lb. of grade C zinc, instead of fixing a price beforehand and ordering the metal as was done in the recent purchase of grades A and B zinc. The reason for this move has not been clear. The bids are to open on Friday and considerable speculation exists as to the price to be paid. As high as 9 to 9.50¢, St. Louis, is generally expected. Grade C zinc is nearly the same as prime Western except that it is a little better as to some impurities. The report of the Geological Survey for the half yearly consumption of spelter soon to be issued is awaited with interest as shedding some light on supply and demand. The market continues in its dull and lifeless condition and quotations are nominally unchanged at 8.10¢, St. Louis, or 8.10¢, New York for prime Western for early delivery or as far ahead as September inclusive. There is no demand and sales are of no volume consumers being unwilling to commit themselves under present uncertain conditions caused by the Government's attitude as to purchasing and price fixing. Those willing to quote beyond September ask from 8.10 to 8.15¢, St. Louis, or 8.10 to 8.15¢, New York. With increased supplies, confidence in the late market is not in the best position. It is hoped that the same time to be made. The total output of zinc is not large.

## ANTIMONY

Antimony and bismuth markets are practically inactive. New York prices are 10.00¢, St. Louis 10.00¢, and the market is not active.

## ALUMINUM

Aluminum is quiet at unchanged prices. New York prices are 10.00¢, St. Louis 10.00¢, and the market is not active.

## Book Reviews

**THE FRONTIERS OF LANGUAGE AND NATIONALITY IN EUROPE.** By Leon Dominian. Published for the American Geographical Society of New York, by Henry Holt & Co., 1917. Royal 8vo., pp. XVIII, 375; pl. ix.; fig. 67.

The outbreaks in Mexico some years ago created such impossible conditions for the mining industry that many mining engineers cast about for other fields of usefulness. The analogous Germanic upheaval has produced similar and world-wide effects, but has differed from the Mexican in sometimes supplying opportunities for mining engineers in lines not immediately connected with mining. The book named above is the result of both these causes. Its author, long a member of the American Institute of Mining Engineers and in active practice in Mexico, became connected, after the Mexican disorders, with the American Geographical Society and turned his early training in Constantinople, his extensive knowledge of European and neighboring Asiatic languages and conditions, his world-wide subsequent experience, and his engineer's disposition to find the solution of a stiff problem, into the prosecution of a study which might indicate a way out of the European difficulties. The book, therefore, is shaped by a desire to emphasize such adjustment of political boundaries as will make for stable conditions. The body of the work sets forth the facts of language and nationality; the concluding pages state the author's solution.

After an introduction by Madison Grant of the Geographical Society, the author summarizes the ancestral races of Europe and the sources of their languages. He then takes up the boundaries of the French and Germanic languages in Belgium, Luxemburg, Alsace-Lorraine, and Switzerland, which constitutes one phase of the problem. The borderlands of the Italian language afford a second and quite individual one. The Scandinavian and Baltic languages furnish a third. The Slavic question with its Polish, Bohemian, Moravian, Slovakian, Hungarian, and several Balkan ramifications, supplies a fourth. The geographical case of Turkey and its various peoples makes a fifth and concluding one. But brief and incidental mention is made of the peoples of central Russia, White Russians, Great Russians, and Little Russians, although the recent evidence of internal disaffection have brought the last two prominently to the fore, a condition of things not easy for Mr. Dominian to foresee. No mention is made of Spain, Portugal, or the peoples of Great Britain, as the boundaries of the last three were probably not believed to be immediately involved in post-bellum settlements. Still, Portuguese colonies bulk large in that extensive area, euphemistically described as Germany's place in the sun, and the same luminary lights up the Moroccan mountains with their prospective copper and iron mines and raises questions which vitally interest Spain.

In the discussion of the various topics, Mr. Dominian adopts first the genetic standpoint so as to make clear the introduction of the several elements of a local population into their present homes. He uses also the statistical treatment based on census reports, and illustrates the relationships by numerous maps and photographs. Many readers will be surprised to learn the complexity of mixtures which the several European States, as at present constituted, have attained. In treating of Turkey and its position at the crossing of the two great inter-continental overland trade-routes, Europe to Asia, and Europe to Africa, the author is particularly well-informed. Altogether the book is supported by wide reading, and is timely, instructive, and of great interest.

The final solution suggested is a grouping of peoples into autonomous states, according to language and national aspirations. A series of buffer-states between France and Germany is advocated, consisting of Belgium, Luxemburg, Alsace-Lor-

raine, and Switzerland, but no guarantees are mentioned to replace the discredited 'scrap of paper.' The author supports the transfer of the Trentino to Italy; a Serbian union of the old Serbia and the provinces along the north-eastern Adriatic which are of Serbian kinship; the addition of German-speaking Austrians to Germany; and the independence of Bohemia and of Hungary. The author thus quite unconsciously demonstrates what all observers of intelligence now realize, that the colossal cuckold nation of the present war is Austria-Hungary. Mr. Dominian upholds the union of the Rumanians, an autonomous Poland, a similar Finland, and the restoration to Denmark of those areas where Danish-speaking people predominate. A solution of the tough problem of the Turkish empire is somewhat vaguely suggested by the establishment of Christian rule, but no specific mention is made of any one Christian nation as sponsor, or of several. Asia Minor is described as practically a German colony, but every intelligent man now knows that Germany is frankly pagan. Odin and Thor, or, one might just as well say, Jupiter and Vulcan, or Zeus and Hephaestus, have replaced the conception of the supreme deity, as taught by Christ. Nevertheless, in so far as they go, the suggestions are of interest and value. In the end they must hold their own in the contest with dynastic and national selfishness, in order to insure stable conditions.

J. F. K.

**LAWS OF PHYSICAL SCIENCE: A Reference Book.** By Edwin F. Northrup. J. B. Lippincott Company, Philadelphia, Pennsylvania, 1917. Pp. 210, index. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

This is an extremely handy book of reference, prepared by a man competent for the task. In fact, the need of such a collection of all the fundamental laws of physics and chemistry, without having to look them up in a number of different volumes, is one that the author himself experienced in his own work in the Palmer Physical Laboratory at Princeton; it was reasonable, therefore, to assume that other men must experience the same need. It covers the field of mechanics, hydrostatics, hydrodynamics, capillarity, sound, heat, physical chemistry, electricity, magnetism, and light; there is also an index, and a bibliography; moreover, the sources of authority are given with each law and the corresponding working formulae. The book is handsomely printed, and is bound most attractively in flexible leather; the dress is in keeping with the character of the contents.

**FATS AND FATTY DEGENERATION. A Physico-Chemical Study of Emulsions and the Normal and Abnormal Distribution of Fat in Protoplasm.** By Dr. Martin H. Fischer and Dr. Marian O. Hooker. John Wiley & Sons, Inc., New York, 1917. Pp. 155, subject and author index, ill. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

The title sounds remote from matters of interest to metallurgists, but science is one, and the principles of chemistry are the same to whatever service we yoke them. In this book, moreover, the physiologic application is separated distinctly from the experimental evidence and scientific conclusions derived from work that may be considered equally apart from direct physiologic associations. In other words the question of the physical character of emulsions was submitted to examination, and the relations of emulsions to the colloidal state of dispersion and of colloidal dispersion-media, were searchingly studied. When it is remembered that Dr. Fischer is one of the eminent colloid chemists of the world, and has been selected by Wolfgang Ostwald as his translator and expositor in English, it will be understood that the data presented in this volume possess the merit of coming from a man qualified to deal understandingly with the phenomena under investigation. We have elsewhere drawn heavily upon the researches of Dr. Fischer in connection with an independent

study of emulsions in relation to flotation. The significance of the evidence adduced by Dr. Fischer to show that control of an emulsion is possible only when the whole of the dispersion-medium is employed in the emulsification, or that the two phases must be wholly complementary, therefore leaving no room for a residuum, could not be lost sight of by the practitioner of flotation. It suggested immediately a new view of the important economic question of control, not alone of the emulsion but of its rate of breaking in order to function properly in the pulp at the moment of producing the gas-in-water dispersion that we call foam, so that the mineral might be floated. Whether the metallurgist may care to read the final chapters on Fatty Infiltration, Fatty Secretion, Natural and Artificial Milk, and Mimicry of Mucroid Secretion, or not, he will be intensely interested in the first half of the work that deals with the important question of emulsions. The style in which the book is written is so charmingly lucid and simple and the subject matter so intensely interesting to cultured men that we believe no student will be able to lay it down until he has read it to the last page.

ANNUAL CHEMICAL DIRECTORY OF THE UNITED STATES. Editor, B. F. Lovelace. Williams & Wilkins, Baltimore, Maryland, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$5.

The enormous development of the chemical industry in this country has been one notable effect of the War, and one that will permanently influence the subsequent life of the nation. The development within two years has surpassed the understanding of the man in the street. We now really have a chemical industry; therefore the appearance of this chemical directory is most timely, and will prove of great value. It is a good performance so far as it goes; it will doubtless improve with the experience of the publishers. We assume that it is what it pretends to be, a directory, intended for the benefit primarily of those who buy it in order to find makers of chemicals and consumers of materials, irrespective as to whether the listed have paid for the privilege or not. It would not be a directory if it made such a discrimination. We mention this because we find some omissions where we have tested it, especially in regard to certain minor products; and it is the minor things that are the most evasive. Everyone knows where to look for Sherwin-Williams when he is interested in paints, although they are not included in this directory (why?), but it might be harder for him to guess that the Krebs Pigment & Chemical Co., for instance, are buyers of zinc and barite with which to make lithophone—and they are not in the book either. It is, therefore, not complete; it is useful, nevertheless, and we hope it will be still better next year than this.

REPORT OF THE ROYAL ONTARIO NICKEL COMMISSION, with appendix. Printed by order of the Legislative Assembly of Ontario. Toronto, Canada, 1917.

We have already given extended notice of this illuminating volume, both in our editorial columns, and by making abstracts of portions of special interest. It now comes in bound form, ready to take the place it deserves in the library, for it is, in effect, the most exhaustive study of nickel from every aspect that has hitherto been printed in English. It covers the history of nickel mining in Canada, and gives an elaborate account of the geology of the deposits; also the deposits in other parts of the world are fully described, in part as the result of personal inspection by the distinguished geologists of the Commission; and finally the volume deals with the metallurgy of nickel and the alloys that have been studied, so that it constitutes the only existing treatise on the metallurgy of this metal that may pretend to be anywhere near complete. As a reference book it will prove of the greatest value to the metallurgist.

## Recent Publications

SANDSTONE QUARRYING IN THE UNITED STATES. By Oliver Bowles. Bulletin 124 of the Bureau of Mines. Pp. 143. Illustrated with half-tone engraving and line cuts. Washington, 1917.

THE MINING INDUSTRY IN THE TERRITORY OF ALASKA IN 1915. By Sumner S. Smith. Bulletin 142, U. S. Bureau of Mines. Pp. 65. One drawing. Index. Washington, 1917.

This volume briefly describes the progress of the mineral industry in Alaska during 1915, reviewing new gold mining districts, gives the mineral production, work at the mine experiment station, new territorial laws, the coalfields, the Government railroad, and gives considerable information regarding the condition in the important older districts. A flow-sheet of the Kennecott copper concentration mill is an interesting feature of the book.

The following publications have been issued recently by the United States Geological Survey:

Professional Paper 97. GEOLOGY AND ORE DEPOSITS OF THE MACKAY REGION, IDAHO. By J. B. Umpleby. Pp. 129, 21 plates, 14 text-figures.

Professional Paper 100-A. THE COAL FIELDS OF THE UNITED STATES. General introduction. By M. R. Campbell. Pp. 36, 1 plate, 3 text-figures.

Professional Paper 108-C. A COMPARISON OF PALEOZOIC SECTIONS IN SOUTHERN NEW MEXICO. By N. H. Darton. Pp. 29, 9 plates.

Professional Paper 108-D. WASATCH FOSSILS IN SO-CALLED FORT UNION BEDS OF THE POWDER RIVER BASIN, WYOMING, AND THEIR BEARING ON THE STRATIGRAPHY OF THE REGION. By C. H. Wegemann. Pp. 6, 2 plates, 1 text-figure.

Professional Paper 108-E. GEOLOGIC HISTORY INDICATED BY THE FOSSILIFEROUS DEPOSITS OF THE WILCOX GROUP (EOCENE) AT MERIDIAN, MISSISSIPPI. By E. W. Berry. Pp. 14, 3 plates, 2 text-figures.

Bulletin 660-A. NOTES ON THE GEOLOGY AND IRON ORES OF THE CUYUNA DISTRICT, MINNESOTA. By E. C. Harder and A. W. Johnston. Pp. 28, 1 plate.

Bulletin 666-P. OUR MINERAL SUPPLIES—ALASKA'S MINERAL SUPPLIES. By A. H. Brooks. Pp. 14.

Bulletin 666-T. OUR MINERAL SUPPLIES—CLAY AND CLAY PRODUCTS. By Jefferson Middleton. Pp. 3.

Bulletin 666-W. OUR MINERAL SUPPLIES—BARIUM AND STRONTIUM. By J. M. Hill. Pp. 3.

Part of Mineral Resources of the United States, 1916, namely: SAND-LIME BRICK IN 1916. By Jefferson Middleton. Pp. 2. Part II. Pp. 2. Geologic Folio 205. DETROIT, MICHIGAN, (WAYNE, DETROIT, GROSSE POINTE, ROMULUS, AND WYANDOTTE QUADRANGLES). By W. H. Sherzer. 22 folio-pages of text, 12 maps, 12 plates, 20 text-figures. Price, 50c. retail or 30c. wholesale. Geologic Folio 206. LEAVENWORTH-SMITHVILLE, MISSOURI-KANSAS. By Henry Hinds and F. C. Greene. 13 folio-pages of text, 4 maps, 10 plates, 10 text-figures. Price, 25c. retail or 15c. wholesale.

MAPS. Topographic maps (about 16½ by 20 in.) of the quadrangles named below are now ready for distribution. Price, 10c. each; if included in wholesale orders amounting to \$3 net, 6c. MICHIGAN, ST. CHARLES: long. 84°-84°15', lat. 43°15'-43°30'; scale 1:62,500; contour interval 5 ft. OREGON, DIAMOND LAKE: 122°-122°30', lat. 43°-43°30'; scale 1:125,000; contour interval 100 feet.

TOPOGRAPHIC MAP OF THE PLATTSBURG TRAINING CAMP. N. Y., 31 by 63½ in.; long. 73°25'-73°35', lat. 44°34'-44°50'; scale 3 inches to 1 mile; contour interval 5 ft. Price, 20c. retail or 12c. wholesale.

# INDUSTRIAL PROGRESS

*Information furnished by manufacturers*

## Automatic Starters for Induction-Motors

Due to the unprecedented demand for manufactured products of every kind, industrial plants in all parts of the country are being taxed to their utmost capacity. In addition, the cost of labor and machinery has been increasing at an extremely rapid rate. The magnitude of these factors has forced manufacturers to employ every means available in an effort to increase production or to reduce operating expenses. This may be accomplished by reducing the number of operators,

by simplifying the duties of the present operators so that more attention may be devoted to the production of a larger quantity and a higher grade of product, or by furnishing better protection to the apparatus installed, thereby insuring continuity of service.

One of the chief factors by which the desired results may be accomplished is the use of automatic starters and controllers for the motor-driven machinery employed. Foremost among the companies producing such control-apparatus is the Westing-

house Electric & Manufacturing Co. similar device for closing the control-circuit, depending upon the service. The vital element is the magnetic contactor. The contactors used on these starters are of a type which has been used by the Westinghouse company with marked success in steel-mill, cement-plant, and mine installations where the requirements are extremely severe. The contactors are opened by strong-spring action assisted by gravity. The destructive action of the arc is reduced to a minimum by strong blow-out coils and arcing-horns.

The operation of the starters is simple. When starting motors driving line-shafting, wood-working and machine-tools, and similar apparatus, it is only necessary to press a button, close a small knife or snap-switch. The starter then automatically makes the proper connections to limit the starting current to a suitable value and to vary the time required for acceleration according to the load on the motor, thus preventing

damage to the machinery by too slow or too rapid acceleration, and saving time by bringing the motor to full speed at the most rapid permissible rate. When used for pump or compressor-service in connection with a float-switch or pressure-gauge, the action of the starters is entirely automatic, the motors being started when the pressure or liquid-level of the tank controlled falls to a pre-determined point and stopped when the desired maximum pressure or level is reached, or vice versa.

The automatic starters for squirrel-cage motors are most frequently employed for starting motors operating centrifugal pumps, air-compressors, fans, blowers, metal-working and wood-working machines, and other apparatus requiring starting torque less than full-load torque. This type of starter, however, owing to the wide application of squirrel-cage motors for industrial service, can be applied economically for starting service in nearly every industry.

Squirrel-cage motors of 5 hp. and smaller are usually connected direct to the line. Large squirrel-cage motors are first impressed with low voltage from auto-transformers or connected to the line through resistance so that in either case the starting current is reduced. When the speed of the motor has reached such a point that the starting current has decreased sufficiently, the motor is then automatically connected to the line.

The automatic starters for wound-rotor motors are particularly adaptable for starting motors driving plunger-pumps, positive pressure-blowers, air-compressors, long line-shafts, and loads having heavy inertia. The severe starting conditions en-

house Electric & Manufacturing Co. at East Pittsburg, Pennsylvania, several of whose starters are shown in the accompanying illustrations. These automatic starters are for use with single-phase or poly-phase squirrel-cage and wound-rotor induction-motors, where it is desired to start the motor from a remote point, or where automatic acceleration is required to guard against improper starting by unskilled operators. They are simple, reliable, and rugged in construction, consisting of a magnetic contactor-panel and a master-switch, which may be either a push-button, a float-switch, a pressure-regulator, or

countered in this class of service require from 100 to 200% full-load torque in starting, making automatic starting a very desirable feature.

When an automatic starter is used in connection with a wound-rotor motor, the line-switch is first closed, with the maximum resistance in the rotor circuit. When the speed falls to a pre-determined value, a relay closes a magnetic contactor which cuts out a part of the resistance in the rotor-circuit. Each contactor operates in a similar manner, cutting out its portion of the resistance at the proper time until all the resistance is short-circuited by the last contactor.

As the power on any circuit may fail suddenly, it is important that some protection be afforded both operator and motor against an unforeseen return of power. This protection may be provided for motors operating pumps, compressors, and other machines, by a low-voltage release to disconnect the motor from the line when the voltage is low or power fails entirely. Then, as soon as power returns, the motor will automatically start up again. In many applications, however, such as for motors operating machine-tools or wood-working machines, low-voltage protection is required. Motors so protected are disconnected from the line when power fails and will not start when power comes on again until the operator presses a button or manipulates a similar device. Hence, there is no danger from the unexpected starting of a machine.

The advantages resulting from the use of automatic starters for induction motors comprise absolute protection to both operator and expensive machinery, proper starting at the most rapid permissible rate, economy in operation and maintenance, convenience of remote control, and automatic operation.

### Acetylene Welding Saves Thousands of Dollars

It has not been so long ago since most plant managers, superintendents, and owners regarded anything thrown into the scrap-pile as waste, beyond reclamation. Probably two things have contributed more than anything else to change their opinions of waste—war and modern welding processes.

In ordinary times the scrap-pile is a neglected avenue for the escape of profits. Now that war has pushed up the prices of raw material to dizzy heights, the American plant owner and factory man have begun to analyze their scrap heaps. Usually they find huge accumulations of damaged or worn machinery, tools, short-ends, and other material that represents considerable profit thrown away. Face to face with labor shortage, metal shortage, and the time factor, plant owners are reclaiming these worn and damaged machines and broken tools, and putting them back to work, earning profits.

Recently an engineer for an oxy-acetylene concern made an investigation in a Western mining field. At one big mine he found in the scrap-piles, dollies and dies for drill-sharpening, worth \$9 each, which could be welded and put into service at a cost of about \$1 each. The mining company was on the anxious seat, too, as to when it would be able to get more new material. It was found that the scrap-heap would yield a three months' supply, of good material, in a year's scrap accumulation.

At another time the engineer found a year's supply of tram-buckets, worth \$40 each, with broken bottoms, that could easily be repaired by welding at a slight cost. He also found a three months' supply of stamp-stems and short ends of tungsten steel, which could be welded and give a year's supply. He found crusher-plates of manganese steel worth \$20 each, slightly too big for the machines then in use, but which could be cut down by the oxy-acetylene process at small cost, and put into service again at a great saving.

The various processes of welding have made it possible to reclaim a large quantity of metal, machines, and tools that formerly were sold as waste at a fraction of the original cost. Nowadays any kind of metal—steel, iron, both cast and malle-

able, brass, bronze, copper, aluminum, sheet-iron, and precious metals such as gold, silver, and platinum, can be welded and broken parts made as good as new.

At a heat of 6300° F., produced by the combustion of acetylene in oxygen, any of these metals fuse and run together, a virtual re-molding of the parts.

A railroad company had a large accumulation of scrapped driving-wheels for locomotives, most of which had cracked spokes. The demand for more rolling-stock, caused by war pressure, caused the company to reclaim these wheels, and the oxy-acetylene welding process did the work, saving the company several thousand dollars and making it much more in profits through putting discarded engines to work.

A big milling concern rummaged its scrap-heap and discovered a quantity of discarded gear-wheels—castings with teeth broken out. At a trifling cost new teeth were fused into the castings, making them as good as new and saving the concern a great deal of time.

America is said to have the biggest scrap-heap in the world, but as conservation is the scrap-heap's worst enemy it is expected to be greatly reduced before the War is over. Perhaps by that time the nation will have learned how to turn metal-scrap into silver dollars.

### Dixon's Graphite-Grease

An interesting use for Dixon's graphite-grease No. 677 and one that is gaining rapidly is its use for lubricating pneumatic tools. The following letter from a user of Dixon's graphite-grease No. 677, who is well known as a consulting engineer for mining and hydro-electric projects, will be of interest to all who have a problem of this kind to solve.

"Lubricating rock-drills is always a problem and an expense. Miners are migratory and the frequent changing of drill operators, when one shift follows another with the same tools, makes the operators careless, for none of them is responsible for the condition of the tools. Therefore the machines lack proper care and use in the first place. The regulation of grease-cups and lubrication is a matter of indifference to the employee.

"Some will pour the oil-chambers full of oil, and run it over, and stop several times to repeat it during a shift—often an excuse to rest. Others will run a drill until it is dry and the hammer sticks, to force a stop. Others will pack the oil or grease-chambers full of any kind of grease, without any effort to regulate the feed, and find that it clogs and does not lubricate.

"The result caused me to look for a grease that was 'fool-proof,' not too thin, so as to run through in a few minutes and be blown out, and not so stiff that it would not feed by itself. So I ordered some of Dixon's graphite-grease, No. 677, for trial.

"This is certainly an excellent lubricant and is efficient and economical, because the men cannot feed it too fast nor too slow, and do not waste it as they do it. It is reducing our drill-lubricating expense over 50% and has shown up best of all the lubricants tried under our laboratory and working tests."

### An Ingenious Chart

The Carrier Engineering Corporation, 39 Cortlandt street, New York, has had prepared a psychrometric chart which enables one to calculate: The amount of heat required to raise the temperature of a given volume of air when saturated or partly saturated with water-vapor. The wet-bulb temperatures corresponding to the various combinations of temperature and relative humidities. The changes in temperatures, humidities, and wet-bulb temperatures caused by the addition or subtraction of moisture. This chart can be used in calculating almost any problem where temperature and the humidity of the atmosphere are concerned.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries in postal union, 25s. or \$6.

Transporting Union Drill over 40 Mile Trail

## These Field Pictures Tell The Story

**The Union Prospecting Drill**  
is incomparably light and can be transported, handled and operated with an ease heretofore unknown for a drill having its capacity.

The Type B Drill shown in the bottom illustration weighs 2150 lb. Drills of this type are drilling 60 ft. ground and deeper, at the rate of 20 to 25 ft. a day, using 5-in. casing, which cuts a 6 $\frac{3}{8}$  in. diameter hole. The engine burns  $\frac{1}{10}$  of a gal. of gasoline per hour.

Every Drill guaranteed.

Bulletin, giving complete description, on request

# EDITORIAL

T. A. RICKARD, Editor

**D**EFENSIVE action against Minerals Separation has been taken in Colorado by organizing a Mill Operators Association with a view to ensuring voluntary financial support and legal assistance for the protection of any member of the Association attacked by the patent-exploiting corporation. We presume, however, that the legal contest over patent rights will be concentrated on the big copper companies, which are the most notable objectors to the payment of a flotation royalty.

**J**OURNALISM and diplomacy alike have been cheapened by the stuff that Mr. Gerard has published in the Hearst and other, better, newspapers. Omitting the Kaiser's telegram, which was intensely interesting and should have been made public by the State Department, not by the ambassador or the syndicate to whom he sold it—omitting that telegram, the rest is no better than kitchen gossip. Most of it is not new and much that is new is trivial. For an ambassador to splash a Hearst paper with large type and larger headings, and thereby spread two-thirds of a column of matter over a whole page, is small business. It is more worthy of a Tammany judge than the envoy of the United States at the Imperial Court of Berlin.

**Z**INC-PRODUCTION has been seriously restricted in response to the dullness of a waiting market. The Government has been unable to determine its future needs, as indicated from week to week by our New York correspondent, and the smelters themselves have taken the practical step of curtailing the output. A mid-year statement from the United States Geological Survey announces that 14 entire plants were idle on June 30, involving a total of 35,000 retorts, in addition to the retorts engaged in refining prime Western spelter and in re-distilling zinc 'ashes.' The market has been further weakened by a slight increase in the production for the half-year, the amount having been 364,000 short tons, or 13,000 tons in excess of the product of the smelters during the second half of 1916.

**I**RON ORE movement by the lake fleet from the North-West involved 10,241,633 gross tons in July, which is the largest tonnage on record, surpassing the shipments in August 1916, the former high level, by 391,493 tons. It is estimated that the requirements of the inland furnaces will exceed 58,000,000 tons this year. Accompanying this large output of ore from the mines, a decline in the production of steel is noted, this being ascribed in part to the hot weather. Timidity in the face of uncertain Government influence upon the market

is another explanation that commends itself as reasonable when it is recalled that the price of No. 2 furnace pig-iron at Chicago, for example, has risen from \$19 per ton on August 1, 1916, to \$55 on the same date this year.

**P**LATINUM is another metal enhanced in value by the War. We hope that the rumored discovery in Alaska will prove true. The price of platinum has risen from \$28 per ounce in 1907 to \$110 at the present time. Its high melting-point, relative insolubility, malleability, and ductility render it particularly useful for the making of chemical utensils. Much of it has been used in dentistry and jewelry. It is to be hoped that the last will become unpopular; for the diversion of platinum for ornament represents waste. In 1915 the United States produced 2329 ounces of the metal and imported 61,437 ounces, the total consumption being valued at \$2,507,183. The world's output in 1914 was 263,450 ounces.

**I**N the current magazines the heroines are discarding elderly financiers and young slackers in order to plight faith with the heroes in khaki, which goes to show that literature is a criticism of life even in its 5-cent form. We have had calls from young engineers out of work and asking for advice how to obtain an appointment. Any unmarried man between 25 and 35 can get the most honorable kind of employment at this time, and wear a uniform that is the most becoming in the world just now. We read the other day about a young man that went to see Joffre and Viviani when they came to New York. The great enthusiastic crowd did not shout either the General's name or the statesman's, they repeated one name again and again, "France! France!" A great longing came over him to hear that name the rest of his life or to hear millions say 'America!' in just that way.

**O**UR contemporary 'The Daily Metal Reporter' draws attention to the fact that the producers of zinc ore are importuning the Government to investigate the conditions under which they have received so small a part of the rise in the price of spelter. This rise is now reversed, the price being about one-third what it was two years ago. The reason for it is to be found in the statistics of export, for whereas the United States exported 230,557,691 pounds in ten months preceding June 30, 1915, it exported 423,474,263 pounds in the corresponding period ended June 30, 1917. Imports are decreasing, from 163,526,191 to 157,386,336 in the ten-month periods of the fiscal years 1916 and 1917 respectively. The imports

have decreased because the contracts for Australian concentrate have been fulfilled and no more is likely to come because the smelting is being done in Australia. Similar efforts to smelt Australian concentrate in England have come to fruition, with the immediate effect of decreasing the demand for our output of spelter, which therefore is being produced at a tremendous rate in face of a sagging European demand. The laws of economics are incorrigible.

**H**YDRO-METALLURGY of lead has developed with exceeding slowness. According to Mr. O. C. Ralston, writing on 'Salt in the Metallurgy of Lead' in the transactions of the American Institute of Mining Engineers, the fundamentals of the process of roasting lead sulphide with salt, followed by leaching with brine, were stated 63 years ago by M. M. Becquerel. He foresaw that such a method would be possible by the application of electrolysis to recover the lead from the solution, but at that time no economic electric generator had been developed. Practically the same method has been studied by Mr. Clarence W. Larson, and the details of plant and technique have been developed by him at the Bunker Hill & Sullivan smelter in Idaho. He tells the story on another page in this issue. It constitutes a step forward in the new metallurgy, and opens a splendid opportunity for an improvement widely applicable in the reduction of lead. Mr. Larson shows that the economic treatment of raw ores containing as little as 8% lead is entirely feasible, when a proper 'mix' has been made to ensure the necessary heat-units for successful roasting. The copper and the precious metals also are dissolved and are precipitated before sending the liquors to the electrolytic vats. The process has been so far perfected that it will soon be in operation on a large scale at the Bunker Hill & Sullivan plant at Kellogg.

**D**ISPATCHES from Washington announce that signs of oil have been discovered on the island Angel de la Guarda in the Gulf of California. This news has created excitement in some quarters and threatens to start a rush to the island. It can scarcely prove agreeable to Carranza, since it would precipitate a crisis between the central Government and the semi-independent administration of Governor Cantú. He has maintained his authority in all essential matters throughout the revolution. An oil-boom in Lower California might bring such wealth and power to the recalcitrant Governor as to provoke a political situation of peculiar interest. Indications of oil are known, not only on the island named, but for a considerable distance along the precipitous coast between the island of San José and Point Concepción, and also across the peninsula between the bay of La Paz on the east and Magdalena bay on the Pacific coast. Serious study of these districts has been retarded by the existence of old titles and concessions that made it necessary to deal with owners who invariably imposed prohibitory terms. The new constitution of Mexico, how-

ever, has 'nationalized' oil-land, that is, it has placed oil under the same rule as metalliferous minerals. Accordingly rights in petroleum have been severed from the ordinary surface-rights, and, the new law being retroactive, it becomes possible now to locate claims wherever indications of oil are found, and to proceed to acquire a leasehold-title from the Government. The new regulations, originally intended to admit of extracting ready cash from the oil-producers of the East Coast, have incidentally opened the way for the adventurous to explore the Lower Californian area, which so long has interested chance visitors to that remote corner of the world.

**U**SUALLY it is ungracious and unprofitable to criticize the published writings of others, but the bulletins of the American Institute form an important part of the technical writing read by mining engineers and metallurgists. If the writing is bad, it sets a poor example. We have received the advance-proofs of a paper written by four metallurgists any one of whom ought to know better than to send such slovenly writing to the Institute; that four men should sponsor such a product is inexcusable, and that the Secretary should allow it to get into print would be incredible if we were not aware that he is over-burdened with his executive duties. We quote: (1) "It is possible in a 15-min. treatment to send off most of the lead and leave a partially roasted pyrite which can be discharged from the downdraft roaster while still ignited, and quenched with water." The incompletely roasted pyrite does well to emerge as quickly as possible from a roaster that is ignited and that is threatened with drowning. (2) "If zinc is present as zinc sulphide, there is not so much danger of overheating the mass with resulting matting of the iron sulphide, and good extractions of the lead are thus possible." The zinc cannot be present as a sulphide of another metal; the mass is not likely to be heated or over-heated with 'resulting matting,' although matting is an inflammable substance in dry weather; the lead is not 'extracted' until later in these metallurgical operations. The four well-informed but careless gentlemen mean that "if the zinc is not present as a sulphide, there is less danger of raising the heat sufficiently to make an iron matte, and a good recovery of lead is therefore practicable." (3) "The proper roast that will allow this is rather too difficult at present for commercial application, but the idea is a good one with which further work might be done." What is the idea hidden behind this verbal fog? Apparently it is meant that "the kind of roasting ensuring this result is too difficult to be economical, but the idea is worthy of further trial." These three quotations, taken almost at random from one paragraph, may not have been revised to express exactly what the authors meant, for they have not taken sufficient pains to make their meaning clear; we give alternatives merely to drive home the criticism. This is not done in any unfriendly spirit, either to the Institute or the four author-members, but to

lay stress on the need for more care in writing. The transactions of the Institute ought to set a good example and gentlemen in responsible positions ought to show their sense of responsibility when they write.

## W. H. Storms

With deep regret we record the tragic death of William H. Storms, the editor of our news columns. On Sunday August 19 he was shot fatally by an old miner, George R. Hutchinson, who had been trying to interest him in a prospect in Placer county. Crazy by his confident hope of selling his mine and demented by disappointment when Mr. Storms indicated his inability to examine it, Hutchinson became angry and in the ensuing altercation used the weapon that he carried in his capacity of watchman on the Key Route railway. It was one of those pitiful tragedies for which no reasonable explanation can be made. The news will come as a horrible shock to the many that knew and liked Mr. Storms. He was widely known and respected among the very class of men represented by the slayer. Born at Hackensack, New Jersey, our late associate was 57 years old. When 19 he went to the Black Hills of South Dakota and there acquired his first mining experience. Then he came to California and lived in the Mother Lode region, being connected with such well-known mines as the Wildman and Black Oak. Drifting into journalism he was connected successively with the Pasadena 'Star' and the San Diego 'Union', leaving the city editorship of the latter in 1891. For six years he was assistant to the State Mineralogist. Then he joined the staff of the MINING AND SCIENTIFIC PRESS, becoming editor under Mr. J. F. Halloran in 1902. He became news-editor when Mr. Halloran transferred his control of the paper to Mr. Rickard, at the end of 1905, and remained on the staff until late in 1906, when he accepted the superintendency of the Yellow Aster mine. He engaged in active professional work as a mining engineer until he was appointed State Mineralogist of California by Governor Johnson in 1911. For this post he was particularly well fitted and he would have discharged its duties efficiently if he had not been dismissed in 1913 by the Governor because he protested against the staff of the Mining Bureau being filled with political henchmen, thereby leaving insufficient funds for field-work. Thereupon he resumed his practice as a mining consultant, but in November last year he re-joined our staff as news-editor. A skilful writer, he was the author of two books, one of which, 'Timbering and Mining', is regarded as a most useful contribution to technology. A kindly and humorous man, he was much liked by his associates. Full of all sorts of information concerning mining in the West, he was always interesting to mining men, but it was among prospectors that he was most at home, as his short stories, published by us last year, testify. We join with his many friends in expressing bitter regret at his sudden end and deep sympathy for his wife and children.

## 'Flotation'

This is the title of a timely book on the metallurgic process that holds the stage at the present time. The authors of 'Flotation' are Messrs. T. A. Rickard and O. C. Ralston. The former, as editor, has done much to make known the fundamental technology of the process, while the latter, as metallurgist in charge of the Salt Lake station of the U. S. Bureau of Mines, has conducted researches as well as collected data on the practice of flotation. This, the latest book on the subject, resembles the one published last year by Mr. Rickard in being in part a collection of articles by many contributors to the MINING AND SCIENTIFIC PRESS. The present volume, however, contains numerous contributions that have not appeared in print before, notably several by Mr. Ralston, of which two are of special value, namely, 'Differential Flotation', and 'Mechanical Development'. As yet the differential treatment for the separation of blende from galena, particularly, has not attracted as much attention here as at Broken Hill, where the Horwood, Lyster, Bradford, and Seale-Shellshear processes have been developed. In the United States the use of froth-flotation in the concentration of copper mineral, particularly chalcocite, has been the outstanding feature, although the success of the process in the treatment of the zinc ore of the Butte & Superior is notable, not metallurgically alone, but because it has furnished occasion for the first big litigation, named after the defendant, Mr. Hyde, and also the third principal suit, against the Butte & Superior Mining Co. The mention of the first litigant recalls the fact that the book has been dedicated, presumably by the senior author, to Mr. James M. Hyde, as "the pioneer of the froth-flotation process in America." Our readers will remember that Mr. Hyde started experimental work in the Black Rock mill, at Butte, in March 1911, and in August he erected a small plant, the operation of which drew upon him the legal attack of Minerals Separation. Disregarding the merits of that quarrel, it is to Mr. Hyde's enduring credit that to his initiative we owed the first demonstration in America of the practicability of froth-flotation; it seems therefore not inappropriate that he should receive this compliment. Returning to Mr. Ralston's contributions to the book, it will be found that the chapter, or article, on the mechanical development of the process reviews the widespread inventive activity marking the last twelve months, for a large number of new machines have been patented and tried. A series of 35 drawings illustrates the diversity of mechanical design. The pneumatic or air-bubbling type, first introduced by Mr. J. M. Callow, is gaining ground as against the blade-agitators of the kind introduced by Mr. E. H. Nutter and others on the Minerals Separation staff. The original machines have been changed and enlarged by some of the big users of flotation, such as the Anaconda and the Inspiration companies, with results not particularly noteworthy. Indeed, we venture to demur against the taking of a ma-

chine bearing a man's name and then widening or deepening it, making it of steel or of bronze, or in some other way departing from the original just enough to excuse the dropping of the inventor's name. However, the big companies are not the only ones to do it. The variations on the Callow machine are already numerous, but the fundamental principle of the porous bottom is common to all of them. That suggests the fact that the Towne patents, in which carborundum was the medium, should prove valuable when the courts have become sufficiently enlightened concerning the difference between bubbling and agitation. This will come in time. Another chapter in the book that is likely to be thumb-marked is the one on the 'Disposal of Flotation Products' by Mr. Robert S. Lewis. This appeared in our issue of April 7 and at the time of publication we complimented Mr. Lewis on the care, and the consequent success, of his manner of writing. He has collected a large quantity of useful information and arranged it in logical form, with explanatory notes. The making of concentrate by flotation is only half the battle, as every millman knows. The concentrate must be sold to a smelter or treated on the spot. Mr. Lewis states how it can be done at home, as it were, and how it is done by the big buyers. Whatever the process of treatment, it is preceded by the dewatering of the concentrate, for the thin slime of finely pulverized sulphide is in no condition for transport. Mr. Lewis describes the multitudinous ways in which the water is drained. Since last year the flotation of oxidized ores has become a live subject and the book says all that can be said just now. It is most suggestive. Another phase of the subject that must not be overlooked is the behavior of colloids, on which Mr. E. E. Price has a chapter, dealing with a recondite subject in admirable form. It is much to be regretted that Mr. Courtenay De Kalb's article on the 'Control of Emulsions', appearing in our issue of August 11, was too late to be included in this volume. Much remains to be done in the study of emulsification as a factor in flotation. Here we may draw attention to Mr. Ralston's discussion of the over-foaming effect in his chapter on 'Flotation-Oils'. As to these we have yet much to learn, particularly concerning the difference in effect between soluble and immiscible oleaginous substances. We know that oil and certain kinds of solids, especially metallic sulphides in a fine state of subdivision, stabilize air films in contact with films of water modified by soluble substances or by adsorbed gel colloids. This introduces a problem that has not yet been definitely answered, namely, what property in common is possessed by oil and mineral particles in the interfacial relation? The hypothesis explaining froth flotation is yet in haste; the practice of the process is ahead of the explanation of it; we are obtaining results long before we know why they are produced; empiricism continues to direct the millman and the physico-chemist follows him with timid steps. In this new book there will be found eight chapters devoted to froth. Several recognized specialists, notably, Messrs.

Wilder D. Bancroft, Joel H. Hildebrand, and Will H. Coghill, have essayed to elucidate the principles of flotation, and Mr. Rickard has contributed 25 pages in which he has endeavored, not without some success, it may be hoped, to interpret the scientific observations of physicists and to render the subject interesting by recording a number of simple experiments, most of which he has tried himself and therefore is able to describe vividly. We welcome the help of such learned doctors as Bancroft and Hildebrand; to them and to their fellow-workers in physical research we look for light upon the many obscure problems of flotation. Here again we take the opportunity to urge a larger measure of co-operation between metallurgists and physicists. The former, of course, ought to know something about physics, but it so happens that the chemical side of metallurgy has absorbed the major share of their attention, so that the sudden growth of the flotation process has taken them at a disadvantage. We need more literature on the physics of the subject, and it must be written as plainly as possible if it is to reach the men that want it, namely, the practitioners. From them, in turn, we ask for more details of manipulation, for those that have studied flotation are keenly aware that manipulation plays an important part in producing successful results within the mill. That is why we welcome such articles as 'Flotation Tribulations' by Mr. Jackson A. Pearce and such clear technical descriptions of mill-work as Mr. Hallet R. Robbins gives in 'Flotation at the Calaveras Copper' mine. None of us knows much about flotation, not even the gentlemen of the Minerals Separation company, and the only way to promote the further advance of this highly fascinating and industrially important branch of metallurgy is to come together in a true spirit of co-operation. That recalls a thought—one not without sardonic humor—suggested by the mention of Minerals Separation. The patentees are scientific men: Mr. H. L. Sulman particularly has proved himself a keen and successful investigator; he and his partner, Mr. H. F. K. Picard, have performed much work of research in the floating of minerals; they and their associates, notably, Messrs. A. H. Higgins, G. A. Chapman, and E. H. Nutter have ascertained much that is worth knowing, but not one of them has contributed voluntarily anything to the knowledge of the subject; on the contrary, they have united not only in keeping secret what they know but also in attempting to place an embargo on the publication of knowledge gathered by others. In consequence, they have seen others discover the main principles underlying the process and they have had to stand aside while others acquired the knowledge that they have withheld, until now the theory of flotation is as well understood, if not better, outside the Minerals Separation office as within its secret portals, and the technology of the process has grown to notable dimensions without their honorable participation in the literature of the subject. Shortly after the first decision in the Mann case, Mr. Nutter said that his company expected to publish a

brochure on the technology of the subject as soon as the litigation was ended; we venture to say that any such brochure will have a mortuary interest by the time indicated, and that it is deeply regrettable not only that the Minerals Separation people should have attempted to wrap the process in secrecy but that they should have tried to compel others, such as ourselves, to abstain from giving forth information so urgently needed by the profession and by the industry to which it is devoted. That is why, among other reasons, we are glad to publish another book on flotation.

## More Manganese Needed

Whoever can produce manganese today can sell it; that is one metal that does not have to pass through the guarded gateway of a 'trust' to reach a market. The extraordinary demand for manganese in the manufacture of open-hearth steel, and the curtailment of available foreign resources, has led to a crisis. The details of the situation are presented elsewhere in this issue. The imports of ferro-manganese have declined from an average of 7577 tons monthly in 1916 to 2717 tons in June, while our domestic output during the same period has shown an insignificant increase from 18,461 to 21,041 tons per month. The average monthly home-production for the first half of this year has been 19,829 tons and the average imports 4916. At the end of June a total monthly tonnage of slightly less than 24,000 tons seemed to be established, whereas the requirements of the steel industry amounted to 28,000 tons. The shortage is so serious that the Alloy Committee of the Council of National Defense has issued a warning to the steel-makers to adopt every possible means for recovery of manganese by the re-smelting of slags, and the substitution of spiegeleisen as far as practicable also has been suggested. The problem, as stated by our correspondent, is to produce a spiegeleisen of low carbon-content. Such an alloy has not yet been produced in the blast-furnace, and it is doubtful whether it can be done in the electric furnace. Could this be accomplished then a great quantity of manganese ores relatively high in iron could be utilized. In making ferro-manganese the reducing conditions in the furnace are maintained by the use of carbon, a part of the carbon being absorbed and tenaciously held as a manganese-carbon alloy. It is possible, when starting with an ore containing about 48% manganese, to hold the carbon-content close to 4%, and with that amount present over-carburization of the steel is avoided, but spiegeleisen contains about the same quantity of carbon, and the ratio of manganese to carbon therefore is nearly double the quantity that can be tolerated. The proportion of manganese to the melt in the open-hearth furnace cannot be reduced, else there would not be enough to serve the purpose of a 'scavenger' through its reducing effect upon the miscellaneous oxides in the iron that is being converted into steel. If a reducing agent other than carbon could be found for mak-

ing a low-manganese ferro-alloy in the electric furnace a satisfactory solution of the difficulty might be reached, but the only metals more greedy for oxygen than manganese, that would be completely eliminated as slag or by volatilization, are too scarce and too costly. Therefore the outlook for making a low-manganese alloy from high-iron manganese ore is not encouraging. The present method of utilizing ores of this class is to mix them with those that are quite rich in manganese. In this way the proper proportions can be obtained. This suggests the possibilities of concentration. In many places the common wet methods of concentration have been successfully applied. The log-washer has been used in the Atlantic States, and jigging also has been employed with considerable success. Magnetic separation has long been used in the concentration of franklinite, and it may have been applied elsewhere. It would seem to offer an opportunity for helping to provide an increased output of desirable manganese ores from a number of relatively low-grade deposits. It would be easy to determine experimentally with a large average sample from any particular deposit precisely what amount of merchantable manganese concentrate could be recovered. The minerals highest in iron would be removable by developing a magnetic field of low intensity, and subsequent concentration by fields of greater intensity would give products of decreasing iron-content with a correspondingly higher percentage of manganese. Such plants, of course, would not be practicable without having large quantities of ore developed, but we have reason to believe that suitable deposits exist, both in Eastern and Western States. Fortunately the construction of magnetic separators is relatively simple, so that it would not be necessary to await the delivery of machines from manufacturers. Greater delay would probably be experienced in securing the needed crushing and sizing equipment. With 40% ore selling at 90 cents per unit, or \$40.32 per long ton, f.o.b. Chicago, or Pittsburgh, it is evident that an ore with a concentration-ratio as low as 4:1 should prove profitable in almost any part of the country. While the chief demand originates in the East it must not be overlooked that 14 open-hearth converters are now in operation on the Pacific Coast, and that a great iron and steel plant is being erected in the State of Washington. The continuance of the steel-industry in the West now seems assured. The Noble Electric Steel Company has responded to the call for ferro-manganese by producing nine tons per day, with a single furnace, in its works at Heroult, California, and it has transformer capacity for making 25 tons of alloy daily. It is only the difficulty of securing electrodes from the East that limits the expansion of these operations. The demand for manganese is becoming more insistent on both sides of the continent, and he who contributes in any detail to the solution of the problem is doing a patriotic service to his country. In California psilomelane is found abundantly in the foothill counties from Tuolumne to Nevada, some of the deposits offering much promise.

## Crisis in the Manganese Trade

Ferro-manganese receipts from Great Britain are rapidly declining and the situation for the steel industry of the United States is not as hopeful as it was. With losses by submarine sinkings amounting to 2000 to 3000 tons in the past two months, and with a more acute situation in England as regards supplies of ore and of the alloy to meet the increased demands of their own industry, future imports from that country are not likely to renew the rate requisite to meet our need of 28,000 tons per month. The May and June available supplies were less than 23,000 and 24,000 tons respectively. Receipts of ferro-manganese from Great Britain in May and June showed a decided falling off from previous months and rendered the situation as to supplies less reassuring than a short time ago. The following table presents the status of the trade, giving the imports and the domestic production of the alloy as shown by the blast-furnace reports in *The Iron Age*, in gross tons.

	Imports	Domestic output	Available supply
Average per month, 1916.....	7,577	18,461	26,038
January, 1917 .....	6,211	21,130	27,341
February .....	6,379	19,942	26,321
March .....	5,324	18,529	23,853
April .....	6,846	17,989	24,835
May .....	2,019	20,722	22,739
June .....	2,717	21,041	23,758

This reveals that the available supply has been diminishing for some time, particularly in the last two months. The average output of domestic alloy has been 19,892 tons per month for the first half of this year. About two months ago the Alloy Committee of the Council of National Defense, after a thorough canvas of the situation, made the statement that the present consumption of ferro-manganese by the steel industry of the United States was 28,000 tons per month. With our production close to 21,000 tons, and with imports at that time reaching about 6000 tons per month, the available supply seemed approximately adequate, but with imports declining as decidedly as they have done, and with no indication of a change, and taking into account the submarine sinkings already reported, the outlook is not as full of promise as it should be.

Realizing this the Alloy Committee of the Council of National Defense has recently notified the steel-industry of this country that not only must every possible effort at conservation of the alloy be made, but that a more liberal use of spiegeleisen must be introduced where feasible. This unexpected development again brings up the question of means to meet this or a worse contingency. It is generally accepted that metallurgically there is no satisfactory substitute for manganese in the important rôle it plays in steel. It has come to be accepted in practice that only the high-percentage alloy is sufficient. Both ferro-manganese and spiegeleisen are high in carbon. Were lower manganese alloys available having a low carbon-content, they would probably be

nearly as satisfactory as the present ones, and would find a wide use.

A solution for the problem, which holds out some hope, is the conversion of our immense stores of valuable manganiferous iron ores into a low-carbon manganese-iron alloy. Blast-furnace reduction does not meet the problem. The electric furnace may perhaps solve it. Important achievements in this field are being accomplished in California. Some metallurgists suggest the value of intensive and prompt research with a view to ascertaining whether such ores cannot be electrically converted into low-carbon alloys. Such a metallurgical process, successfully carried out on a commercial scale, would be of incalculable value to the great steel industry of the United States and perhaps would render us independent of foreign sources of manganese. Its feasibility at least deserves thorough investigation. For high-grade ore, from which to make ferro-manganese, the United States is absolutely dependent on foreign countries. Before the War, Russia, India, and Brazil were the sources of this supply; now Brazil has stood almost alone as our help in greatest need, sending in 1916 over 500,000 gross tons. The dependence of this country upon Brazil or other outside sources of supply is appreciated when it is known that only 80,000 tons of such ore will be available in 1917 from the United States as against a theoretically necessary supply of 700,000 to 800,000 tons per year.

ALTHOUGH the 'permissible explosive' list of the Bureau of Mines is intended for coal mining, the regulations in large part are of general application. An explosive is called 'permissible' when it is similar in all respects to the sample that passed the tests by the Bureau of Mines, and when used in accordance with the conditions prescribed, but even explosives that have passed those tests and are named in the list as permissible, are to be so considered only when used under the following conditions: (1) That the explosive is in all respects similar to the sample submitted by the manufacturer for test; (2) That detonators, preferably electric detonators, are of not less efficiency than those prescribed, namely, those consisting by weight of 90 parts of mercury fulminate and 10 parts of potassium chlorate, or their equivalents; (3) That the explosive, if frozen, shall be thoroughly thawed in a safe and suitable manner before use; (4) That the quantity used for a shot does not exceed 1½ lb. (680 gm.), and that it is properly tamped with clay or other non-combustible stemming. An explosive, however, is not 'permissible' if kept in a moist place until it undergoes a change in character; if used in a frozen or partly frozen condition; if used in excess of 1½ lb. per shot; if fired with a detonator of less efficiency than that prescribed; if fired without stemming; and if fired with combustible stemming. The Bureau of Mines permissible list contains many varieties which would be useful in metal mining, and increase the tonnage broken, particularly where the ground was not so hard as to require the stronger grades of explosive.

# The Flotation of Gold and Silver Mineral

By T. A. RICKARD

In the title to this article I have avoided the use of the word 'ore,' because the object of flotation is to float not the 'ore' but the valuable mineral in the ore, leaving the gangue to sink. It is a selective process, based upon the idea that the ore consists of valuable and of valueless components, which must be separated so that the valuable component may be concentrated as cleanly as possible previously to a final treatment in which the metal or metals are extracted and prepared for the market.

Some of the earliest work in flotation, such as that at the Glasdir mine, in 1896-1899, was done on an ore containing gold and silver, but the recovery of the precious metals was incidental to the concentration of the chalcopyrite with which they were intimately associated. Likewise the saving of the silver in the Broken Hill ore was incidental to the recovery of the sulphides of lead and zinc. In such cases—and they are typical—the floatability of gold and silver in the native state, or of their mineral compounds, does not present any special problem because the recovery of the gold and silver follows the concentration of the base-metal sulphides by which they are usually so closely accompanied in ore deposits. However, the floatability of native gold, as of native silver, hardly needs special demonstration here. 'Float gold' has been a bugbear of processes in which water is used, whether in the sluice-box of the gulch or in the stamp-mill on the hillside. Small particles of gold, particularly when flaky, are easily transported on water, as every miner has learned to his sorrow. The platy form of gold, so common in veins, lends itself readily to flotation, if the particles are small, by offering a large surface to the play of surface-tension and to the adhesion of air. The high metallic lustre of gold is a characteristic that experience in flotation would lead us to associate with easy buoyancy in the presence of air and of oil. If the gold is 'rusty,' that is, coated with iron oxide or with manganese di-oxide, or, as more rarely happens, with a film of silica, we should not expect it to float, as we should not expect it to amalgamate or to cyanide freely, until it had undergone such abrasion as would expose a fresh clean surface. Similarly gold in a clayey ore may make trouble for any process in which water is used, but this, like the 'rustiness,' is nothing new and is not peculiar to flotation.

As regards silver, the same general ideas apply. Silver in flaky form is elusive when running water is used, because it is readily floated; likewise when it presents a clean surface it is easily amenable to the guidance of the ascending bubbles. One would expect native silver and those of its compounds that are either highly lustrous, or have a marked cleavage, to float easily. This is a fact.

Experiments made at Cobalt\* showed a recovery of 92 to 97% for metallic silver, 77 to 89% for argentite, 85 to 87% for pyrargyrite, 78 to 80% for proustite, and 69% for fieslebenite. These experimental results have been confirmed in practice, a recovery of 96% having been made by using oil-flotation to supplement gravity-concentration.† Of manganiferous silver ores, a type familiar to the Mexican miner, it can be stated that when they cannot be cyanided they also cannot be floated. The obstacle probably is the double oxide of silver and manganese. Even preliminary sulphidization appears ineffective because the sodium sulphide will not attack the manganese-silver compound.

As regards the economic gold minerals, namely, the tellurides, they are so lustrous that one would expect them to be eminently floatable. That would apply to the silver tellurides also. Such has been the experience at Cripple Creek, provided, of course, that oxidized ore is carefully excluded from the mill-feed. At the Vindicator mine the practice is to wash the oxidized material out of the ore before it goes to the flotation plant. At the mines on the Mother Lode, in California, where the carbonaceous slate causes trouble by re-precipitation of gold in the cyanide solution, it has been found advantageous to apply flotation after amalgamation.

However, even if sundry gold and silver minerals will float, that does not mean that they can be recovered successfully as a concentrate by the frothing process. Direct floatability would refer to the surface-tension methods, such as those of Wood and Macquisten.

For the success of the older methods, such as that introduced by the Minerals Separation company, employing mechanical agitation, it is necessary that the pulp should contain finely divided mineral able to pass into the oil-water interface and in quantity sufficient to stabilize the air-bubbles by armoring them. Thus, a clean gold-bearing quartz is unsuitable to a machine working on the principle of violent agitation unless, of course, it contain enough gold, so sub-divided by the time it reaches the flotation-cell as to suffice for froth-making. The tailing from a vanner is not as suitable for the agitation-froth process as the pulp before it has undergone concentration on the vanner. Similarly, a gold-quartz ore containing 5% gold-bearing pyrite or other sulphides is better adapted to agitation-frothing

\*Canadian Mining Institute. Bull. No. 62. J. M. Callow and E. B. Thornhill.

†At Cobalt the flotation-cell has replaced the slime-table in the McKinley-Darragh mill, while in the Nipissing, Buffalo Mines, and Dominion Reduction mills the cyanidation of tailing has given way to re-grinding and flotation.

than one containing 1% only. This applies to the mechanical stirrer; it does not apply to the pneumatic machine, in which air-bubbles, supplied lavishly, rise quietly through the pulp. In such a machine it is not necessary to have a large proportion of mineral for stabilizing the froth because the plentiful supply of bubbles obviates that requirement. As one bubble breaks, another is ready to take its place, so that the float, or concentrate, does not fall, but is lifted successively until it passes over the lip of the cell.

Another important phase of the subject is the recovery of the base metals associated with the precious metals. In mills using amalgamation and cyanidation, the presence of base-metal sulphides may be so detrimental that an ore containing any considerable percentage of them is likely to be left in the mine. In some cases the presence of base-metal sulphides, insufficient to be a source of revenue, but sufficient to interfere with the milling, has rendered it unprofitable to treat an ore. For such mines the use of flotation comes as a real boon. In the San Juan region of Colorado at this time there is a pronounced growth of productive activity because flotation has facilitated the recovery of the base metals associated with the precious, and so long as the metal markets remain propitious, we may expect a further expansion in this direction. Flotation is superior to any of the older wet processes—amalgamation, chlorination, and cyanidation—in that it will enable the miner to recover not gold and silver only, but copper, lead, and zinc as well.

These general remarks will serve to introduce some analyses of specific conditions—a more satisfactory method of discussing a problem that is economic as well as scientific.

#### NORTH STAR MILL

In the early part of 1916 the management of the North Star Mines, at Grass Valley, undertook a critical analysis\* of the milling methods then in use, with a view to consolidating the existing plants and obtaining greater economy of treatment. The ore was being reduced in two 40-stamp mills, each with a cyanide annex, situated at the two main openings of the mine. The combined capacity of the two plants was 110,000 tons per annum, development work during 1915 had been highly successful, and it was anticipated that by centralizing the entire plant at one shaft a considerable saving in operating expense might be made.

The ore was being crushed by 1050-lb. stamps to pass 20-mesh screens, the treatment involving amalgamation in the mortars and on plates, then table concentration, followed by classification into sand and slime for separate cyanidation. The concentrate was re-ground in tube-mills to pass 200-mesh and treated in the slime-plant. The total extraction averaged \$10 in gold per ton of ore; of this, \$5 was obtained in the stamp-mortars, \$3 on the amalgamating plates, and \$2 from the concentrate, sand, and slime. The tailing averaged 25 to 35 cents per ton, so that the extraction averaged 97%. To

treat 108,000 tons in 1915 the cost of milling was \$51,000, for cyanidation \$42,000, a total of \$93,000, besides the tailing-loss of \$30,000—a total deduction of \$123,000.

Whatever process might be adopted, it was deemed advisable to retain amalgamation, since fully 50% of the gold extracted was caught in the mortars and 30% on the plates. It seemed wise to use amalgamation to catch as much of the free gold as possible early in the operations, as a sportsman tries to shoot his bird with the first barrel rather than the second.

The necessary experiments in flotation were made by the firm of Hamilton, Beauchamp & Woodworth, of San Francisco. Samples of plate-tailing were sent to them. The assay-value of these samples ranged from \$2.50 to \$2.90 in gold per ton. The first tests indicated that the material required re-grinding, to pass 80-mesh, in order to obtain a good recovery in the flotation-cell. When the heading assayed \$2.50 the residue from these tests ranged between 10 cents per ton on pulp ground to 200-mesh, and 40 cents on pulp reduced to pass 65-mesh. When the plate-tailing was ground to pass 80-mesh the flotation residue averaged 25 to 30 cents per ton, like the residue after cyanidation.

The treatment of the flotation concentrate was the next step in the investigation. To ship the concentrate to a smelter—the Selby smelter, near San Francisco—would cost \$17 per ton, for sacking, haulage, freight, treatment, and losses. This cost, on an ore containing 3½% sulphides, would mean 50 cents per ton of ore. Smelting therefore was not to be recommended. There remained the possibility of cyaniding the concentrate. The ratio of concentration being 30 to 1, the flotation product was worth from \$70 to \$90 per ton. The residue from the working-tests, when cyaniding the flotation concentrate, averaged \$6 per ton. The average consumption of cyanide was 6 lb. per ton. Experiments were made also to learn what effect the flotation-oil had on the precipitation of the gold or on the fouling of the cyanide solution. The results indicated that no difficulty was to be anticipated from the presence of small quantities of oil in the concentrate.

Given the results of these flotation experiments and comparing them with the results obtained in cyanide practice, it appeared that three methods were available for use in the consolidated plant, which was to treat 110,000 tons per annum:

No. 1. To use 60 stamps of 1500 lb. each and crush to 0.04 inch diameter, employing amalgamation, classification, concentration of the sand, the classifier overflow and the concentrator tailing each going by separate conduits to the cyanide plant; the concentrate to be re-ground to 200-mesh and to undergo separate treatment in the cyanide annex, in order to ensure sufficient contact with the solution before being delivered to the slime-plant.

No. 2. To use 40 stamps of 1500 lb. each, crushing to 8-mesh, followed by amalgamation, classification, and re-grinding; to re-grind 70% of the stamp-product in tube or ball-mills to pass 80-mesh, this product to be treated

\*For this information I am indebted to William Hague, managing director of the North Star Mines.

by flotation, re-grinding the flotation concentrate to 200-mesh before cyaniding it.

No. 3. The same as No. 1 except that, instead of cyaniding the slime, to treat everything finer than 150-mesh by flotation and to leach the coarser material with cyanide solution; the flotation concentrate to be cyanided with the re-ground product of the water-concentrators.

Tests made in the mill showed that the 1500-lb. stamp falling 6 inches 105 times per minute would crush a little more than 5 tons per day to 0.04 inch, the screen having an open area of 36%; and also that this weight of stamp, crushing to 8-mesh, would have a duty of  $7\frac{1}{2}$  tons, yielding a product 70% of which would be coarser than 80-mesh.

The question of using ball-mills, both as primary and secondary crushers, had to be considered. The fact that

\$27,000, plus a loss of \$20,000 more (3300 tons of flotation concentrate per annum in which \$6 per ton would be left after cyanidation) in the residue of flotation concentrate after cyanidation. The total deduction would be \$116,000.

No. 3 required an operating cost of \$75,000, plus a total tailing and residue loss of \$39,000, making \$114,000. In this estimate, as in No. 2, royalty has not been included in the operating cost.

The capital cost to be incurred was estimated at \$52,000 for No. 1, \$42,000 for No. 2, and \$50,000 for No. 3 method.

It was decided that the saving of \$15,000 per annum to be made by consolidating the plant, under No. 1 method, was justified, this decision being strengthened by the disadvantage, occurring under No. 2 and 3 meth-

THE MELONES MILL, CALAVERAS COUNTY, CALIFORNIA

50% of the gold could be saved in the mortars was favorable to the retention of the stamps. Furthermore, in referring to descriptions of South African practice, it was noted that from 5 to 10% less gold was recovered by amalgamation after coarse crushing followed by tubemilling was introduced. If 5% more of the gold in the North Star ore, formerly saved by amalgamation, were thrown into the cyanide annex, the extra loss in cyanidation would off-set the saving of power and supplies to be anticipated from the substitution of ball-mills.

In estimating the operating cost of the 60-stamp mill and cyanide annex, the management was able to supplement its own experience with that of a neighboring plant having a capacity equal to that of the one being planned. In estimating the cost of flotation treatment, the North Star management was less confident, having to depend largely upon the advice of others; but by giving due weight to the evidence available it was possible to come to a fairly trustworthy conclusion, namely:

No. 1 method, applied to 110,000 tons in one year, involved a working cost of \$75,000, plus a tailing-loss of \$33,000, making a total deduction of \$108,000.

No. 2 would require a working cost of \$69,000 on the same tonnage and in the same time, plus a tailing-loss of

ods, of having "to choose between paying a royalty or fighting a patent suit."

#### A MEXICAN MILL

Next I shall quote figures relating to a silver mine in Mexico. The question had arisen of substituting flotation for cyanidation. Experiments, made by the same firm as had tested the North Star ore, indicated that this Mexican ore was amenable to flotation. The silver sulphides floated readily; the recovery ranged from 70 to 83% of the combined silver and gold, varying according to the proportion of oxidized minerals in the ore—oxidation being a deterrent to flotation, of course. This compares with an extraction of 91% by the existing method, which gives 77% of the metallic content as bullion and 14% as concentrate. But a closer analysis of more detailed data is required to make a trustworthy comparison. The present method of treatment includes crushing in cyanide solution followed by concentration of the sand on Wilfley tables and of the slime on Deister tables, re-grinding the sand and cyaniding an all-slime product. The capacity of the plant is 150,000 tons per annum and the ore assays \$10.50 per ton when silver is worth 65 cents per ounce. The ratio of gold to silver in the ore is

10 oz. silver to 0.07 oz. gold. The tailing is worth \$1 per ton. The total cost of milling is \$1.55 per ton, to which must be added 10 cents per ounce of fine metal for marketing the bullion, this charge including export-tax, expressage, and refining, and 15 cents per ounce of metal for marketing the concentrate, this expense including taxes, freight, smelting, and sacking. The present output yields a bullion 700 fine and approximately 50 tons of \$350 concentrate per month.

On the other hand, the flotation plant would cost \$50,000 and would produce 100 to 150 tons of \$500 to \$800 concentrate, to be marketed at a cost of 15c. per fine ounce and leaving a tailing assaying \$2.10 per ton. The Mexican export-tax on concentrate is 2% (of gross value) more than on bullion, thus:

	Bullion, %	Ore, %
Federal .....	5	7
State .....	2½	2½
	—	—
Total .....	7½	9½

The final comparisons are as follows:

1. Between table-concentration followed by cyaniding and straight flotation, the saving in cost of treatment by flotation is about equal to the extra recovery by tabling and cyaniding, but the increased expense for marketing the large tonnage of lower-grade concentrate plus lower smelter-returns on concentrate than on bullion represents a loss of 90 cents per ton of ore by straight flotation.

2. Between table-concentration and cyanidation, as against flotation and cyanidation of flotation tailing, the extra recovery is 33 cents (extraction 94%) and the saving in cost is 57 cents per ton, while the additional expense of marketing the concentrate plus lower smelter-returns on concentrate than on bullion is 90 cents, so that the difference is extinguished.

Cyanide is taken at 30 cents per pound, 1.8 to 2 lb. being consumed per ton of ore. Lately the precarious character of the cyanide supply has furnished an argument in favor of flotation. Packing the concentrate on mule-back or freighting it by train, with the uncertainty of getting cars for shipment to a smelter, possibly outside Mexico, are points requiring careful consideration. On the other hand, a load of concentrate is less easily stolen by revolutionists or brigands than a bar of bullion. The smelter deductions are important; usually payment is made on 95% of the silver and \$19 (or 91.92%) is paid per ounce of gold in the form of concentrate against 100% of these metals in the form of bullion. This represents a net loss of 6 to 8% on this class of ore. At present therefore it is inadvisable to spend \$50,000 in erecting a flotation plant to obtain a result no better than that given by the existing system of treatment, but it may prove advantageous in the future to adopt flotation followed by cyanidation when the flotation product itself can be treated safely and profitably on the spot, yielding bullion. This example will serve at least to emphasize the fact that such problems cannot be settled in the laboratory, and to show that the object of metallurgy is to give the greatest net returns rather than the highest percentage of extraction.

## THE MELONES MILL

Another interesting comparison between cyanidation and flotation is afforded by an investigation made by the Melones Mining Company, which treats a low-grade gold ore typical of this part of the Mother Lode region. The existing plant consists\* of 100 stamps weighing 1000 lb. each, and dropping 6 inches at the rate of 107 drops per minute. The stamp-duty, when discharging through a 20-mesh screen, is 5.3 tons. No plate-amalgamation is attempted inside the mortar, but mercury is fed into the battery, and the pulp when discharged passes over the usual amalgamating tables. The ore, a gold-bearing quartz containing pyrite, averages \$3.65, from which \$1.83, or 50%, is extracted by amalgamation and cyanidation, leaving a 51-cent tailing and 3.4% of concentrate assaying \$36 per ton. The further extraction of the gold in the concentrate may be disregarded for the moment. Of the total extraction 43% is obtained as amalgam, 17% as bullion in the cyanide annex, and 40% in concentrate, which also is treated by cyanidation. The pulp from 60 stamps passes from the amalgamating tables to Wilfley concentrators, while that from the new mill of 40 stamps undergoes classification in spitzkasten before being concentrated. It has been observed in the Mother Lode region that the pulp from the stamp-battery does not concentrate so well after hydraulic classification as without such preliminary treatment. Sizing seems to be preferable. On the Wilfley tables the gold-bearing pyrite is recovered as a concentrate; at the same time, by the addition of extra water in the feed-box of the Wilfleys, the sand and slime are separated without the intervention of the usual de-sliming classifiers. The sand, assaying \$1.15, goes to the leaching-vats of the cyanide annex; the slime, assaying \$1, passes through cone-classifiers, the underflow from which joins the sand in the leaching-vats, while the overflow runs to the slime-plant. This includes Dorr dewaterers and Devereux agitators,† followed by Dorr thickeners and an Oliver filter. A middling, assaying \$8 per ton, is made on the Wilfleys; this, after classification, goes to six 'finishing' Wilfley tables, the tailing from which is passed to the sand-plant.

The following facts are pertinent to our enquiry. The Wilfley tables recover 95% of the gold that is so intimately associated with the pyrite as to have escaped amalgamation; such gold-bearing pyrite as escapes into the cyanide annex is either in the form of slime or it is material that has been insufficiently pulverized. The pulp after concentration on the Wilfleys assays \$1.12, whereas the mill-tailing, discharged from the cyanide annex, assays 51c. per ton. That represents the residual loss, to which must be added the loss in the treatment of the concentrate. The 'sand' and 'slime' are nearly equal in weight. The extraction of gold from the 'sand' and

\*For most of the information in these paragraphs I am indebted to W. G. Devereux, manager for the Melones Mining Company.

†For a description of these machines see M. & S. P., March 3, 1917.

'slime' together is about 55%, that is, 55% of the 31% of gold remaining after amalgamation and concentration. A solution containing  $\frac{1}{2}$  lb. KCN per ton of ore is used in cyaniding the slime, and a 4-lb. solution on the sand. The total cost of milling (excluding concentration) is 50 cents per ton of ore.

What can flotation do on this ore? Samples were sent to the Minerals Separation people in San Francisco and they reported thus:

	Weight	Gold	Recovery
	%	oz.	%
Heading .....	100.0	0.06	100.0
Concentrate .....	1.4	1.83	42.7
Middling .....	6.2	0.20	20.7
Tailing .....	92.4	0.02	30.8

that the ore as submitted can be given flotation treatment usefully," but it must be noted that the sample "as submitted" was much too coarse to undergo successful flotation. The extra cost of re-grinding to 200-mesh is a vital factor in the problem. What would be the cost of re-grinding? At a neighboring mine, producing a similar ore, the cost of re-grinding is 25c. per ton. But all the pulp would not have to be re-ground; only the sand, say, 275 tons in all, out of the daily output of 530 tons. At 25c. per ton on 275 tons, the cost per original mill-feed would be 12c. per ton for re-grinding.

A flotation plant to treat 530 tons of such ore would cost \$6000 f.o.b. San Francisco, or \$10,000 erected; but the necessary re-grinding plant would cost \$20,000 more.

THE APP MILL, TUOLUMNE COUNTY, CALIFORNIA

This showed a recovery of 63.4%, including the middling, which, in mill-practice, would be re-treated continuously. However, account is rendered for only 94.2% of the total gold in the heading. The material tested was slime from the Wilfley tables, the screen-analysis showing 98% through 200-mesh. In a later test, made at the same laboratory, a sample of the pulp as it came from the amalgamating tables was subjected to flotation, the result being a failure owing to the coarseness of a large part of the product. After the sample had been re-ground, until only 4% remained on a 200-mesh screen, the flotation machine did as follows:

	Weight	Gold	Recovery
	%	oz.	%
Heading .....	100.0	0.085	100.0
Concentrate .....	1.7	4.400	88.4
Tailing .....	98.3	0.010	11.6

The chief engineer (E. H. Nutter) for Minerals Separation reported that this test "indicates very definitely

The items of operating cost are estimated, by Mr. Nutter, as follows, per ton of dry ore:

	Cents
Reagents .....	6
Labor .....	5
Power (35 hp. per 200-ton unit) .....	2
Royalty at 25c. per oz. gold .....	2
	15

To this must be added the present cost of crushing and amalgamation, which is 20c.; so that the total cost of combined treatment, to the point of making a concentrate, would be

	Cents
Crushing .....	20
Re-grinding .....	12
Flotation .....	15
	47

This compares with the present cost of 50c. Allowing a 90% recovery by flotation, as against the present 86%,

on a \$3.65 ore, the additional winning would be 14.6c. per ton.

The Melones concentrate, representing 3.4% of the weight of ore, is re-ground, at a cost of 50c. per ton, to pass 200-mesh and is then cyanided, without roasting. The cost of treatment is \$5.50 and the extraction is 92%. The cost is 19c. per ton of crude ore and the tailing retains 9½c. in gold.

In making this comparison the treatment of the concentrate is assumed to be the same, whether it be the product from the Wilfley tables or from the flotation-cells. No doubt exists as to the successful treatment of the flotation concentrate, which would not require re-grinding, so that the present cost of re-grinding the concentrate, which is 50c. per ton of concentrate, or 1.5c. per ton of mill-feed, would be saved. Moreover, the concentration would be higher, if one may judge from the results of the test made on the re-ground pulp. In that experiment the concentrate was only 1.7%, but it assayed \$88, that is, it was half in quantity and double in richness as compared with the Wilfley product. Apparently the re-grinding had liberated some gold, which had become included in the concentrate; on the other hand, some of the quartz attached to pyrite had been loosened so as to join the rest of the gangue in the tailing. The reduction in the weight of concentrate would decrease the cost of treating concentrate from 19c. per ton to, say, 15c. The higher-grade concentrate would require more careful handling, and the extraction, at the same ratio of 92%, would leave a higher residue, namely 8% of \$88, or \$7.04, as compared with 8% of \$36, or \$2.88, making a difference, however, of only 2c. per ton of original ore, owing to the higher rate of concentration by flotation. In the event of adapting flotation to a stamp-mill, such as that of the Melones, it would be advisable to take the pulp from the amalgamating tables to the re-grinding machinery, in preparation for flotation, and not to attempt any table-concentration, because flotation would be better when leaving the pyrite in the pulp than when treating pulp after concentration. It only remains to remark that the Melones treatment might be changed to all-sliming and cyanidation, discarding concentration and separate treatment of the concentrate.†

The cost might be reduced 3c. per ton, but it must be remembered that the flotation figure is only an estimate as against the actual cost by the existing method. The increased extraction might be 15c. per ton. The total gain, of 18c. per ton, would be attractive if confirmed by further experiment, and if the use of flotation did not involve inquisition by, and subservience to, a patent-exploiting company. That undoubtedly, in my opinion, is a deterrent now. If it were a question of erecting a mill on a mine that had no reduction plant, and that produced ore of the kind we have been discussing, it would be rational to adopt flotation, not only for the sake

of the small extra extraction but on account of the first cost of plant. The Melones cyanide plant cost \$50,000.

#### THE DUTCH-APP MILL

At the Dutch and App, a neighboring group of mines, in Tuolumne county, a conventional Californian mill of 40 stamps of 1050 lb. each, followed by amalgamation and concentration, has been changed from concentration by Wilfley tables and Frue vanners to flotation, so that a closer comparison is possible. I am informed‡ that the cost in the old mill was 74 cents, of which 38c. was for stamping, amalgamation, and concentration, and 36c. was for the transport and treatment of the concentrate. The Californian custom of reporting the cost of milling without including the expense of realizing upon the concentrate is misleading; so also is the practice of ignoring the loss or smelter-deduction from the assay-value of the concentrate. This item should be added to the assay of the mill-tailing in order to ascertain the total loss, and therefrom the total extraction of valuable metal. Thus the total cost in the old mill was 74c.; in the modified mill it was found to range between 88c. and \$1 per ton. The modified plant, however, is at best a mill patched-up for the purpose of testing the ore by flotation; therefore, the cost should be much reduced. The tonnage treated was at the rate of 200 tons daily, whereas the proposed new mill will treat 600 tons daily.

The tailing in the old mill, treating daily 200 tons of \$3.75 ore, assayed 90 cents (excluding the loss in concentrate-treatment), but when flotation replaced concentration by Wilfley tables and Frue vanners on the same grade of ore, the tailing was reduced to 35c. during the first month of operation, showing a saving of 55c. per ton. The comparative cost of a plant to treat daily 200 tons of ore carrying 5% of concentratable pyrite is estimated under normal conditions as follows:

(1) Twenty stamps of 1250 lb. each, with two re-grinding tube-mills, plates, and vanners—including rock-breaker, \$48,000.

(2) Same mill, using flotation in place of vanners, \$55,000.

(3) Same mill, concentrating on tables; the sand and slime treated by cyanide, \$65,000.

No. 3 does not include the treatment of concentrate, because it is the usual custom to send it to the smelter at Selby. It will be noted that, for a comparison of plant-cost, No. 3 must be compared with No. 2. Flotation has given a slightly higher concentration of the gold-bearing pyrite in the Dutch-App ore; thus:

Old mill, 4½% of \$35 to \$40 concentrate.

Flotation, 5% of \$50 to \$65 concentrate.

The cost of transport and treatment is 38c. per ton of ore. The cost of haulage, freight, and smelter deductions is \$9.50 per ton of concentrate. The cost of stamp-crushing and ball-mill re-grinding together is 35c. per ton. The cost of flotation by itself is 15c., making 88c. per ton in all for the extraction of the gold.

†Compare this with the Nickel Plate experience. "The Nickel Plate Mine and Mill." By T. A. Rickard. M. & S. P. January 20, 1917.

‡By W. J. Loring, who, I hope, at a later date, will contribute his own testimony on the subject.

When the new mill is treating 500 to 600 tons daily, it is expected to reduce the cost to 68c. and the tailing-loss to 20c. per ton.

By way of further comparison I may quote the cost of milling at an up-to-date plant, using stamps, amalgamation, and table-concentration, namely, at the Plymouth Consolidated in Amador county, also on the Mother Lode. There the cost of milling is 36c. and the concentrate realization 24c. more, making 60c. per ton. The treatment is most satisfactory because, among other reasons, the yield of concentrate is only 1½%. On such an ore flotation would not be as beneficial as on the Dutch-App ore, which contains 5% concentratable gold-bearing pyrite.

#### THE ARGO MILL

A tribute to the elasticity of the flotation process is furnished by the use of it in a plant treating custom ores. In the Argo mill, at Idaho Springs, Colorado, it has been found highly advantageous to substitute flotation for cyanidation, after stamp-milling and classification, as shown on the accompanying flow-sheet.\* Most of the ore comes through the Argo (formerly Newhouse) adit, which taps the veins of Clear Creek and Gilpin counties. These contain gold and silver associated with pyrite, chalcopyrite, and tetrahedrite, so that it is a question of concentrating the sulphides encasing the precious metals. Much of the ore is of the so-called 'free-milling' kind, that is, it is amenable to stamp-mill amalgamation. The coarse gold is caught on the tables before flotation; the fine gold is caught in the flotation concentrate. Good results are obtained by classifying before flotation, particularly on oxidized ore. A trial on an oxidized gold ore from the Paris mine yielded 86% by flotation and 98% by cyanidation. The mill levies the same charges for treatment as the smelter at Denver and has helped, by its competition, to lower the smelter-rates. Its own concentrate is sold to the smelter. Rens E. Schirmer, the manager, and Jackson Pearce, the metallurgist, informed me that they are able to treat ore assaying \$40 to \$80 per ton. They quote \$10.50 for treatment on a \$50, and over, ore, but the bulk of the custom ores that come to this mill range between \$9 and \$20, gross value, and on such material the milling-charge ranges from \$4.75 to \$5.50 per ton.

For zinc there is no pay and also no penalty.

For lead they pay the regular smelter rate, namely: "Deduct 1.5% from wet assay. The prices paid per unit for lead ore are based upon a quotation of \$4 per hundred pounds, 1c. up or down for each change of 5c. in this quotation, which shall be 90% of the sales prices in New York of the A. S. & R. Co. for common desilverized lead, provided said price does not exceed \$4 per hundred pounds. When price does exceed \$4 per hundred pounds, the quotation used as a basis of settlement shall be \$3.60

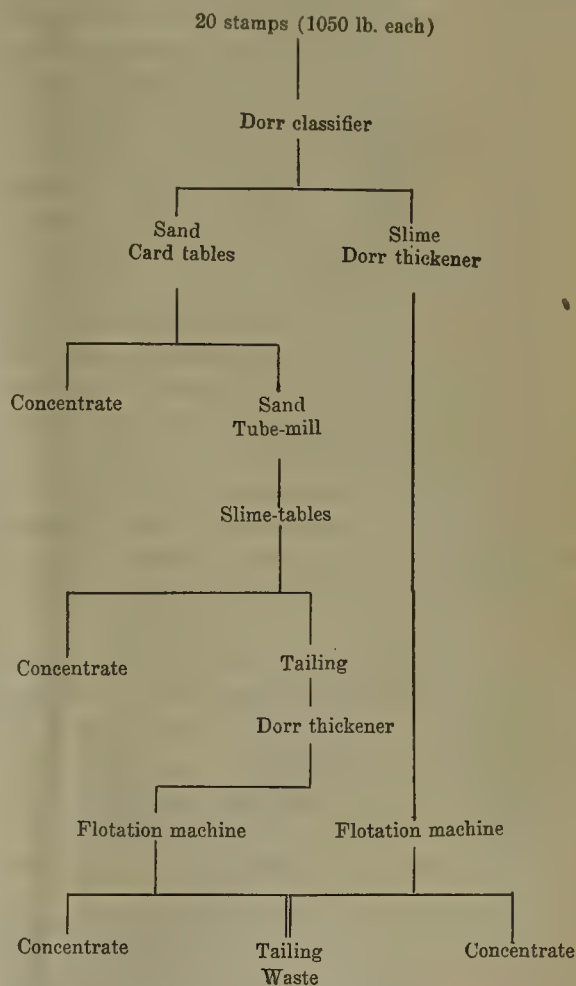

\*See also an excellent article by Jackson A. Pearce. 'Flotation Tribulations.' M. & S. P., Sept. 16, 1916.

†I quote the exact words in order that the reader may appreciate the hocus-pocus of this smelter method of fixing the price of lead. It is to laugh!

per hundred pounds, plus three-fourths the excess of said sales price above \$4 per hundred pounds."†

For copper they pay on the dry assay, that is, 1% deduction from the wet assay, and the Western Union quotation for casting copper, less 6c. per pound.

For silver, they deduct ½ oz. from assays up to 10 oz. per ton, and pay for the remainder at 95% of New York quotation on date of assay. For ore over 10 oz.

FLOW-SHEET OF ARGO MILL

per ton, they pay 95% of the quotation, without further deduction.

For gold they pay \$19 per oz. between 0.05 and 1.5 oz. per ton; on richer ore they pay \$19.50 per ounce.

The Argo mill, with its flotation annex, has treated 4 oz. gold ore, 100 oz. silver ore, 40% lead ore, and 5% copper ore at different times. Such high-grade ore is mixed with the lower-grade before being milled. Money has been made even on a \$1.25 ore.

It was found that the recovery by flotation was slightly better than by cyanidation; moreover, the cost was lower, owing to the less expense in chemicals. A much simpler flow-sheet became practicable; there is less pumping, less

power, and less labor. Hence the adoption of flotation. A further and decisive advantage is the ability to beneficiate the base metals, notably copper, which was a cyanide. Since flotation was introduced the mill finds a wider scope and is able to command a larger custom. The flotation machine in use is one devised and patented by Mr. Pearce. It is of the mechanical agitation type, but it consumes less than one third of the power required by the Minerals Separation machine previously used in this mill. A 6 cell Pearce machine requires only 5.3 horse power. Two such 6 cell machines are employed, one to treat sand (80% + 200 mesh) and the other to treat slime. The former gives the higher recovery. I watched them at work and can testify that they produced a uniformly good froth and appeared to be operating admirably. Two pounds of an oil mixture, consisting of two parts of gas oil to one part of pine-oil (Pensacola Tar & Turp. Co.'s No. 400), is used per ton of ore. The gas oil comes from Wyoming; it is one from which the lighter gasoline has been removed. The more sulphuric an ore the larger the proportion of oil required. As soon as sulphuric particles appear in the tailing, more oil is added. Gas oil costs 6c. per gal. and pine oil 32c. laid down. The water is neither acid nor alkaline. Neither acid nor alkali is added. Fresh water is used, there being no return of water from the tailing. By using fresh water the millman avoids fouling of the liquid by an accumulation of colloids. Formerly the overflow from the concentrate-thickener was run back to the flotation-cell but it was found that this closed circuit tended to collect colloids detrimental to a high recovery by flotation.

Experiments have been made with as much as 40 lb. oil per ton of ore; the recovery was slightly higher than when using 2 lb. per ton. What a commentary on the 'critical' point! When using 40 lb. of oil the bubbles are smaller owing to the larger proportion of gas oil, which was increased to 85% of the oil-mixture. When using 5 to 6 lb. oil and storing the concentrate in a wooden bin, Mr. Pearce noticed that the oil seeped visibly.

Ordinary variations of temperature appear to have no effect. In winter the froth freezes occasionally, so that it sinks, but so long as the temperature is just short of freezing the operation is not affected. In summer the recovery is no higher than in winter. The mill recovers 92% of the gross market-value of the various ores and treats 100 tons daily.

#### THE PORTLAND MILL

As yet scarcely anybody that has tried flotation has discarded it after trial. One example of such a reversal is furnished by the Portland Gold Mining Co. of Cripple Creek, and the reasons for it are interesting.

The ore was dump material assaying \$2.25 per ton, carrying half an ounce of silver for every ounce of gold, both minerals being present as tellurides, chiefly calaverite. After treating over 100,000 tons the management decided that flotation was not superior to their older

method of treatment by table-concentration and cyanidation, for the following reasons:

(1) Good extractions are obtained by cyanidation when grinding to 20-mesh, whereas flotation calls for grinding to 48-mesh. This extra work costs 10c. per ton, which is a serious item on \$2.25 ore.

(2) Cyanide bullion is sold to the Mint, and the small amount of concentrate that is made is so low in silica and so high in iron that it can be marketed at the smelter on easy terms, whereas flotation yields a large amount of silicious concentrate on which the cost of freight and treatment is three times that of marketing the by-product of a cyanidation mill. On this ore the recovery by flotation was found to be inversely proportional to the grade of the concentrate; a high recovery made a large amount of low-grade concentrate; a small amount of high-grade concentrate entailed a poor recovery.

(3) Only \$20 per ounce was paid for gold in the flotation concentrate, and nothing for the silver. Cyanide bullion is sold to the Mint at \$20.67 per ounce for gold and 95% of New York quotation for silver. Thus 4% more is received for the product from the table-concentrate than for the flotation product. On account of the highly silicious character of the latter it was found that the cost of marketing at the smelter was out of all reason, whereupon it was sent to the custom roasting-cyanide mills at Colorado Springs. This flotation concentrate proved ideal stuff to treat after roasting, but as the silver is not recoverable after the ore has been roasted, the mill could not pay for it.

(4) The royalty payable to the Minerals Separation company.

The principal difficulty was to make a high-grade concentrate and a low tailing concurrently. Amorphous slime rises with the froth, and any effort to prevent it involves a loss of the sulpho-telluride mineral; in short, it is difficult to separate the gangue-slime from the mineral in this particular ore. Any free gold in the ore floats with the telluride and sulphide minerals. Incidentally, it is worthy of note that flotation in cyanide solution was accomplished successfully at the Portland by J. M. Tippet. He had to use caustic soda, in preference to lime, in order to ensure sufficient alkalinity. The ore was ground in the presence of caustic soda and cyanide. Mr. Tippet avoided dewatering, and the consequent loss of cyanide, by establishing a closed circuit. The pulp flowed from the flotation-cells to thickeners and pachuca, and thence to filters. By this method of treatment he was able to obtain a 40c. tailing on a \$20 ore. From \$17 to \$18 was taken off in the form of a 12-ounce flotation concentrate, the tailing from which assayed \$2 or \$3 per ton and was reduced to 40c. by treatment in a pachuca.

#### SUMMARY

In most cases the substitution of flotation means the making of a concentrate instead of bullion. The latter is ready for the market and easily handled or transported. The concentrate is bulky and if it has to be shipped else-

where for treatment the handling of it entails loss, to which must be added freight and smelter deductions. However, these are troubles that can be obviated if the concentrate is treated at the mine. Some difficulty is said to have been caused by the oil retained by the concentrate; it may interfere with cyanidation, as Paul W. Avery testifies,\* but we have the statement of E. M. Hamilton† that he has treated several samples of flotation concentrate with complete success. The experience at the Melones mine is to the point. Speaking generally, I infer that if an ore can be cyanided, then its concentrate, obtained by flotation, can also be cyanided successfully. In short, any gold and silver ore that can be amalgamated or cyanided is amenable to flotation, and the resulting concentrate is equally amenable to treatment by cyanidation. In some cases, as with Cripple Creek tellurides and the Cobalt silver minerals, it may be necessary to roast first, but the use of flotation on precious-metal ores need not involve dependence upon a smelter. That is important. On the concentrate made at Cobalt, for example, the total cost of marketing is \$38 per ton. A chloridizing roast followed by leaching appears to be the only escape from this exaction. In California, the marketing of concentrate from a Mother Lode mine involves a cost, in freight, treatment, and other deductions at the smelter, of \$9 to \$15 per ton. This can be avoided, at many mines, by cyanidation on the spot without roasting, at a cost of about \$5 per ton. It is remarkable how little enterprise has been shown in this department of ore reduction, despite the obvious saving of money promised by such a departure from precedent.

Thus we see that the substitution of flotation for the older processes of amalgamation and cyanidation is an economic rather than a metallurgic problem. In most of the specific cases discussed in detail it is safe to assume that if the manager were starting today to equip his mine with a mill, he would select the flotation process rather than the older methods, or make flotation a part of his flow-sheet. The scrapping of an existing, and expensive, plant is quite another matter. Usually the simple flotation plant would cost half that of the more complicated cyanide annex. Yet, in conversation with various managers, I have ascertained that the control or assumed control of the basic flotation patents by the Minerals Separation people is a strong deterrent. Most of us do not like to be inquisitioned by the agents of a patent-exploiting company, nor do technical men care to be placed under pledges of professional secrecy to anybody. The royalty on gold is only 25 cents per ounce and on silver  $2\frac{1}{2}\%$ , so that the tax is not onerous, but a tax of any kind is an irritation to most men, particularly when the right of the tax-gatherer is still undecided by the courts of law. If and when this question of Minerals Separation's right to collect a royalty is decided satisfactorily we may expect a wide extension in the application of flotation to ores chiefly valuable for gold and silver.

## The Thiogen Process

Recovery of sulphur di-oxide from smelter fume has for several years engaged the attention of the Bureau of Mines. These studies have included a critical investigation of the wet thiogen process. The results are given in the Bureau of Mines Bulletin 133, prepared by A. E. Wells. In carrying out the thiogen process the gases are first cooled and cleared of dust and fume. They are passed through an absorption-tower in which the sulphur di-oxide is absorbed in water or mother-liquor. To the solution of sulphur di-oxide is added powdered barium sulphide, when there is precipitated barium sulphite, thio-sulphate, and sulphur; the precipitate is settled and the mother-liquor returned to the absorption-tower. The settled precipitate is then filtered and dried. The elemental sulphur and one-half the sulphur from the thio-sulphite are distilled and the sulphur vapor condensed. The residue, consisting of a mixture of barium sulphite and sulphate is then reduced to sulphide, which is returned to the operation as a precipitate. In the investigations made, all the operations involved in the process were studied, not only on a laboratory scale but on a scale that may be considered semi-commercial, so that the technical possibilities of the process were determined. The results indicate that the process can be carried out successfully. However, in the reduction of the barium to sulphite it was found that there is a tendency for the formation of barium oxide and carbonate, which will react slowly in the precipitation. These compounds tend to increase in amount, as the barium is used in a cyclic operation. The proportion of these insoluble barium compounds can be reduced to a low figure by rapid reduction with pure carbon at a high temperature in a furnace or retort externally heated. In any case, as the soluble barium compounds increase in successive cycles the soluble barium sulphide can be leached out and the insoluble compounds allowed to react with strong sulphur di-oxide solution, resulting in their conversion to sulphite or sulphate, which can subsequently be reduced to the sulphide. The conclusions are that in some places the process can be conducted successfully for the recovery of sulphur and sulphur di-oxide from waste smelter-gas on a commercial scale at a cost of about \$1 to \$13 per ton of sulphur produced.

I. W. W. SABOTAGE.—In an interview published in the *Oregon Journal*, J. P. Weyerhaeuser, of Tacoma, manager of extensive timber interests, said: "I recently asked one of the I. W. W. leaders what his people wanted, anyway." "We want your mill," was the reply. Asked what he would do with the mill after he got it inasmuch as none of his organization knew how to run it the response was: "That doesn't worry us; we will have plenty of time to learn to run the mill after we get it." That seems to be the spirit of the crowd. They are out to disorganize and disrupt legitimate business. Do you know that practically all the men in the lumber camps this year are working on 'slow orders'?"

# Properties of Vanadium Steel

By G. L. NORRIS

\*A prevalent idea credits vanadium with being a powerful scavenger, and ascribes the beneficial effects of its use in steel principally to its action in removing minute residual amounts of oxygen and nitrogen from that metal. It has even been advanced by some that when all the vanadium added has been completely used up in scavenging, and none remains in the steel, all the improvement or beneficial effect it is capable of yielding has been accomplished, despite the fact that there is an increase in the mechanical properties of the steel with increasing amounts of vanadium present, and that vanadium has equally as beneficial effects in steels made under reducing conditions, such as crucible and electric-furnace steels, as in the case of those made under oxidizing conditions, like open-hearth and bessemer-steels. While it is true that vanadium oxidizes readily and will combine with nitrogen, its value as a scavenger is negligible, as there are far cheaper metals that are equally effective, or perhaps more so. The remarkable effects of vanadium on steel are due entirely to its presence in the steel as an alloying element and its influence on the other constituents with which it is in combination. It is found in both the main constituents, ferrite and pearlite, but principally in the latter. Only a few hundredths of one per cent of the vanadium combines with the ferrite. This minute amount, however, appears to increase the strength, toughness, hardness, and resistance to abrasion, of the ferrite. Nearly all the vanadium, however, is found in the pearlite, in chemical combination with the cementite, as a compound carbide of vanadium and iron in the case of ternary steel, and as more complex carbides in the case of quaternary steels.

Vanadium replaces the iron in the cementite or the carbide by increasing amounts until, finally, when the amount of vanadium is about 5%, all the iron is found to be replaced by the vanadium. The vanadium-containing cementite is not as mobile as ordinary cementite and consequently does not segregate into as large masses, but it occurs in relatively minute particles, and, therefore, is more uniformly distributed. It does not, consequently, readily occur as lamellar or thin plates in the pearlite, but in a granular or sorbitic condition. This strong tendency of vanadium to form sorbitic and even troostitic pearlite is doubtless one of the reasons for the mechanical superiority of steels containing vanadium, not only statically but dynamically. Vanadium carbide is not as readily soluble on heating as iron carbide, and consequently vanadium steel requires a higher temperature to dissolve the cementite and to put the steel into the austenitic condition for quenching.

The effect of vanadium on the physical or mechanical

properties of steel increases with the percentage of vanadium until about 1% is present, after which there is a decrease, even in the case of quenched steels, and with 3% or more of vanadium the steel is actually softened on quenching except at unusually high temperatures, such as 1300° to 1400°C. Vanadium steel hardenite has a greater thermal stability, that is, power to withstand elevated temperatures without softening or breaking down or without separation of the cementite. This property is responsible for the great improvement in high-speed steels through the addition of vanadium enabling it to stand up longer under the high temperatures developed at the point of the tool in taking heavy cuts at high speed. Percentages of vanadium as high as 3.50 have been successfully used in high-speed steel, and 1.50 to 2.50% are not uncommon, although only a few years ago the percentage ranged from 0.30 to 0.75, and it was thought that the addition of over 1% gave little additional advantage. The improvement in high-speed steel through the use of vanadium has borne an almost direct relation to the percentage of vanadium present, and is considered to be from 60 to 100%. In the case of carbon-vanadium tool-steel, the use of vanadium has proved almost equally beneficial, although at present only about 0.2% of vanadium is used in such steel. It has a wider quenching-range, that is, it can be heated higher without injury; it hardens deeper, retains its cutting edge longer, and is much tougher and stronger. A bar of 1% carbon tool-steel containing 0.25% vanadium, quenched and drawn back at 400°C., will bend 90° without failure, whereas a similar steel without vanadium will bend only about 20° or possibly 30°. Comparative compression tests of such tool-steels, with like tempering or draw-back, gave on 1½-in. cubes, 490,000 lb. for the vanadium steel and 278,000 lb. for steel without vanadium. For battering-tools, such as pneumatic-chisel, setts, calking-tools, rock-drills, etc., vanadium tool-steel possesses marked superiority on account of its combination of hardness, strength, and toughness.

One of the principal applications of vanadium steel has been for steel castings, particularly for locomotive frames. The addition of this small amount of vanadium increases the elastic limit of the annealed castings 25 to 30%, without lowering the ductility. The tensile strength is not increased proportionately in the case of thoroughly annealed castings, but is usually 10 to 15% greater. Vanadium-steel castings require a somewhat higher annealing-temperature than ordinary steel castings. They are also more susceptible to hardening, and therefore should be cooled slowly in the annealing furnace. The annealing temperature should be about 875°C. in this case.

\*Abstract: *Iron Age*, July 19, 1917.

THE BUNKER HILL &amp; SULLIVAN SMELTER

## Hydro-Metallurgy of Lead-Silver at the Bunker Hill Smelter

By CLARENCE L. LARSON

Although the hydro-metallurgy of lead has been discussed in technical articles and has been the subject of patents, no appreciable results have hitherto been obtained on a commercial scale. During the past three years, however, a serious study has been made of the possibilities of developing some kind of a wet process for lead ores. Although contributions to the progress of the method have been made by others, the Bunker Hill & Sullivan must be credited with the major effort, in which the research work of various earlier experimenters has been utilized. The Bunker Hill & Sullivan investigation has been directed toward the production of bullion from its lead-silver sulphide ore at its plant at Kellogg, Idaho. The process under consideration involves, in the main, four steps: (1) roasting, (2) leaching with saturated brine, (3) direct electro-deposition of the lead from the brine-lixiviant, using soluble iron-anodes, (4) regeneration of the brine-lixiviant.

The rejuvenation of the Holt-Christensen chloridizing-process for copper, silver, and gold ores, which is virtually the Longmaid-Henderson process with new mechanical apparatus, contributed the first item of note to the present study. In the Holt-Christensen leaching experiments at Park City, Utah, lead was detected in the mill-solutions. At the Knight-Christensen mill at Silver City, Utah, Christensen again observed lead in the solutions, and though the lead in the ore treated was usually inconsiderable, a deposition of such as was carried in the solution was highly desirable, since its recovery would be clear profit on the custom contracts. Accordingly Christensen did some experimental work with iron electrodes. This appeared encouraging, but before the results could be verified on a larger scale the mill burned

down and that terminated Christensen's active work on lead. In the Park City plant Holt had also carried on some small-scale work, but had reported unfavorably. In August, 1914, I began an examination of the Holt-Dern system of blast-roasting, doing my work in the Bureau of Mines laboratories at the Department of Metallurgical Research, in the University of Utah. In a couple of months my tests verified the Holt-Dern claims as to operating on low-grade copper, silver, and gold ores. In testing the American Flag ore at Park City, a nearly perfect extraction of lead was obtained. I then suggested to D. A. Lyon, the Director of the Station, that this be followed up, and that a study be made on the behavior of zinc ores under similar treatment. He heartily approved, and to him is due credit for steady co-operation in counsel and in experimental work along this line. Considerable investigation followed throughout the year 1914-15, both on lead and zinc, with distinctly encouraging results on the lead ores but with decidedly discouraging results on zinc. During this period a sample of vanner-tailing was secured from the Bunker Hill & Sullivan, and the successful roasting of this material led to my joining the staff of the Bunker Hill & Sullivan Mining & Concentrating Co. in July, 1915.

At this time the Bunker Hill & Sullivan Co. was experimenting on a small scale with a process, an outline of which is as follows: the ore was chloridized in a Dewey hearth-furnace; leaching of the roasted product followed, utilizing saturated brine as a lixiviant; slaked lime was then used to precipitate the lead, after which the lead-precipitate was filtered off and re-dissolved in acetic acid, the resulting solution being electrolyzed between graphite-anodes and lead-cathodes. This work developed

many difficulties both in practice and in economics. The roasting was inefficient and expensive; the lime-precipitation was awkward in regulation and operation, and produced a low-grade product; the silver did not precipitate well; the lead-precipitate was difficult to wash free from salt; the electrolysis was expensive and the electrolyte degenerated rapidly. Worst of all, the brine-lixiviant fouled rapidly in cyclic use. These difficulties forced a shut-down of the experimental plant, and much laboratory study followed, resulting in the development of the process that will now be described, and which promises to be satisfactory from an economic standpoint.

Roasting tests on lots of 500 to 1000 lb. were made on various mill-products and on mine-run ore, in a Holt-Dern intermittent type of blast-roaster. This is the type which was used at the plant at Park City in 1914-15 on copper, silver, and gold.\* Ore, dry-crushed to the proper mesh, is mixed with fuel if necessary, and with salt if desired, and then with water. This gives the 'roaster-

decrepitated during the roasting, whereas the Bunker Hill material does not. In the latter case it appears to be necessary to crush through at least No. 20 mesh. The size of the material greatly affects the mechanical conditions of the roasting operation. In order to make the matter more clear a description of the test-roaster is presented. Fig. 1 gives detail drawings of the furnace shaft, and Fig. 2 of the grate used. The roaster is essentially a shaft-column of concrete with an open top for charging and a closed bottom, with suitable doors for discharging the roasted product and for cleaning under the grates. The grate-details are assembled as seen in Fig. 2: the beveled posts are used to support the notched strips, while into the notches are fitted thirty  $\frac{1}{2}$  in. by  $1\frac{1}{2}$  in. by 30 in. strips. Thus is formed a grating of  $\frac{1}{2}$  in. spacings. This is covered with a depth of three or four inches of  $\frac{3}{4}$  in. down to  $\frac{1}{2}$  in. tailing, in order to prevent the wooden grate from burning. A positive-pressure air-blast is provided under the grates, the 5 in.

FIG. 1

mix'. An essential condition in the roaster-mixes is that the size of mesh to which the ore should be crushed must be such that the particles properly react in roasting. Bearing in mind that brine is to be the leaching agent, it is evident that it is essential to transform as much lead sulphide into chloride and sulphate as possible, with a minimum production of oxide. In my experience two kinds of galena have been observed. That derived from the Eagle & Blue Bell mine in Utah roasts efficiently when crushed to No. 8 mesh, and Bunker Hill ore, if crushed to No. 8 mesh, also will roast in an apparently satisfactory manner except that all of the coarser particles of the galena will be found unchanged in the calcine. It seems that the Eagle & Blue Bell galena

by  $2\frac{1}{2}$  ft. by  $2\frac{1}{2}$  ft. space serving as an equalizing chamber. Above the level of the wooden grate with its cover of tailing comes the calcine-discharge door. This is luted air-tight with fire-clay during the period of roasting.

The method of roasting is as follows: Upon the grate is built a fire of kindling, the air-blast being utilized to burn the wood until only live glowing coals remain. These are spread evenly over the entire area of the grate. The air-blast is now turned off, and the wet roaster-mix is dropped in and spread evenly over the fire to the desired depth, which may vary from 12 to 40 in. The air-blast is again turned on, and the roasting proceeds, 6 to 20 oz. air-pressure

being required. When the fire-zone has broken through the entire surface of the charge the calcine is drawn and the roaster is ready for another charge.

Returning to the subject of size of crushing, the finer the mesh the greater the difficulty in getting a charge introduced so as to have uniform air-permeability throughout its entire mass; also, the slower the roasting the lower the capacity per square foot of grate-area. The size of the crushed ore also has an effect on the fuel required to roast the mass, for the finer the particles the more perfect become all the reactions with the metal sulphides, thus increasing the realizable fuel-value of the ore. The fine material also requires a greater height of roast-column and a higher air-pressure than the coarser sizes. With the increased air-pressure the danger of getting blow-holes or chimneys through the charge becomes correspondingly greater. Crushing should be done by rolls rather than by ball-mills because sharp angular particles tend to increase the permeability of the ore-bed in the roaster. The fuel-factor of the roaster-mix is apparently of the utmost importance in the blast-roasting of lead ores. Galena always shows a fuel-value dur-

\*Bibliography on Holt-Dern roasting: U. S. Patents on the Holt-Dern Process, No. 1,107,240, 1,113,961, and 2; Bull. A. I. M. E., July 1914, 'Chloridizing Leaching at Park City,' by T. P. Holt; M. & S. P., Aug. 29, 1914, 'Rejuvenating the Chloridizing Roast,' by F. Sommer Schmidt; *Eng. & Min. Jour.*, Feb. 6 and 13, 1915, 'Chloridizing Blast-Roasting and Leaching,' by Glenn A. Keep; U. S. Bureau of Mines, Technical paper 90; *Mex. Min. Jour.*, May 1915, 'The Holt-Dern Process,' by C. L. Larson.

ing the oxidation of the lead sulphide. Pyrite also possesses considerable fuel-value, but other factors of ore-composition may lessen the heating-effect of the galena and pyrite contents. For instance, the gangue may contain inert constituents having high specific heats. Two analyses of ore follow:

	B. H. & S. mine, %	Alhambra mine, %
Lead .....	8.28	8.04
Lime (CaO) .....	0.26	0.74
Iron .....	16.20	21.75
Silica .....	48.15	32.10
Sulphur .....	3.26	3.14
Manganese .....	1.43	1.47
Alumina .....	2.36	11.00
Zinc .....	0.98	0.20
Copper .....	tr.	0.44
Silver, oz. ....	3.50	8.40

These ores come from adjacent properties. The Bunker Hill & Sullivan ore, with no addition of fuel, tends to roast too hot. The temperature is so high as to sinter the charge pronouncedly, and the result is to cut down the silver recovery from 30 to 50% and the lead recovery from 10 to 20% below the results obtained under suitable conditions. The Alhambra ore requires the admixture of  $1\frac{1}{2}$  to 2% of coal-dust in order to blast-roast it successfully. Its high alumina-content is undoubtedly responsible for this fuel-requirement. In order to modify the high temperature produced by an ore that contains too high a fuel-value it becomes necessary to use a diluent. To the Bunker Hill & Sullivan ore has been successfully added some calcine from a previous roast, or a highly silicious mill-tailing containing lead and silver. If the mixing of ores or material carrying mill-products were not possible, inert rock of high specific heat could be used, perhaps coarser in size, so that the calcine might be screened and the coarse particles of diluent returned to the roasting charge. If an ore requires fuel, another ore containing an excess fuel-value, or pyrite, or coal-dust must be added. Rarely will as much as 2% of coal-dust be required. About 2% of pyrite is equivalent to 1% of coal-dust, although pyrite has the more beneficial effect on the reactions desired. The limits of fuel-value in the roaster-mix are (a) maximum, the first indication of sintering, and (b) minimum, a tendency of the roast not to spread evenly to the furnace walls on all sides. Suitable calcine is pulverulent, shows no trace of sinter, and exhibits a distinctive red-dish-blue color. Calcine showing deep black particles with a shiny lustre is not good, as it contains lead compounds insoluble in everything except hydrofluoric acid. Sintered material also prevents the recovery of any silver. In the blast-roasting of lead ores, (and this involves low-sulphur content by reason of the type of roasting) it seems advisable to add salt to the charge. The following table indicates the general experience in such tests:

Kind of roast	Neutral brine, extraction		Acidified brine, extraction	
	Lead, %	Silver, %	Lead, %	Silver, %
No salt .....	70 to 80	0	75 to 85	20 to 30
2 to 7% salt ...	80 to 90	50 to 65	88 to 95	80 to 90

The ores assayed from 8 to 11% lead and 4 to 10 oz. silver. Muffle-roasting or hearth-roasting of high-sulphur ore has been found to give practically perfect lead-sulphating results on galena without the use of salt. The roasting of carbonate-ore is distinctly different from that of sulphide-ore. I attempted to blast-roast a lead-carbonate ore from the Wilbert mine in Idaho, which has about 6% lead and a trace of sulphur. Chloridizing was first attempted, and after varying every factor in the mix and in the operation, it was concluded that lead oxychlorides had formed during the cooling period. Tests made on cooling roasted calcine in air-tight chambers seems to confirm this theory. Sulphidizing of the lead in this ore was then tried and an efficiency of 80% was attained by an addition of 10% of pyrite.†

The water required in roaster-mix charges varies from 5 to 15%. Fine sizes require more than coarse, and clayey ores more than silicious ones. For the most part water has proved to be a not very important factor in

FIG. 2

POSTS FOR WOODEN GRATE

the roasting of lead ores. Care need be taken only to the extent of merely moistening all the slime-particles of the mix. In Hofman's 'General Metallurgy' will be found the detailed reactions occurring in a chloridizing roast. In this discussion I limit myself to the formation of lead chloride, lead sulphate, lead oxide, sodium and manganese sulphates, and insoluble iron oxides. Upon the addition of a leaching solution or of a preliminary water-wash, all chloride of lead is changed to sulphate in the presence of sodium sulphate, so that the solubilities involved in leaching are those of lead sulphate. The Holt-Christensen process utilizes a 22° Baumé brine for a mill-solution in work on copper, silver and gold ores. Solubility-tests on lead sulphate readily show the necessity of using a saturated brine in the leaching of roasted sulphide-ore, or of carbonate-ore if sulphuric acid be used with the brine. A solubility-curve seen in Fig. 3 shows tests made at 15° and with freshly made brine and pure lead sulphate. A maximum concentration is noted of 15 gm. per litre. All work done to date in cyclic leach-

†The Department of Metallurgical Research at Salt Lake City has performed interesting work in the direct acid-brine leaching of carbonate-ores. Some of the early work done at that laboratory is reported in the *Met. & Chem. Eng.*, Oct. 1, 1916, 'Electrolytic Recovery of Lead from Brine Leaches,' by Sims and Ralston.

ing indicates that this will be about the maximum that will be attained. The use of saturated brine in the leaching of calcine involves, in cyclic work, a gradual building up of the sulphates in the solution. This rapidly lowers the possible lead concentration and lessens the speed of leaching. Iron also builds up to about 20 gm. per litre and then maintains a practically constant concentration, but no effect of this iron has been noted. Removal of the accumulating sulphates at suitable intervals, or after each cycle, effects a regeneration of the lixiviant to its original power.

As soon as the fouling of the brine with sulphate was proved, attention was directed toward minimizing the quantity of the sulphates that might go into solution. Tests showed that, from average calcine, about one-half of the total brine-soluble sulphur could be removed by a water-wash without incurring loss of lead or silver.

FIG. 3

The economics of this step were such as to warrant the inclusion of a preliminary water-wash as an integral step of the process. Cyclic leaching showed that as soon as the sulphur-content rose above 5 or 6 gm. per litre, the deterioration of the lixiviant became evident and rapidly increased, accompanied by further concentration of the sulphur in the solution. By the time the sulphur-content reached 10 to 12 gm. per litre the dissolving of the lead grew infinitely slow and the resulting solution nearly worthless.

Elimination of sulphur may be accomplished by direct precipitation with calcium chloride, but such a step in most places would not be economically favorable. Slaked lime is used and causes elimination of sulphur according to the following reactions:

The precipitate of calcium sulphate and iron hydroxide must be filtered off. Should any lead remain in the solution subjected to this regeneration it would be precipitated and lost. Consequently this step is utilized only after the lixiviant has been completely stripped of lead. In order to produce a pure marketable bullion it is necessary to remove all the copper and silver from the brine-lxiviant previous to sending it to the electrolytic vats, as any remaining silver or copper would there precipitate upon the depositing lead and upon the iron electrodes. Numerous precipitants have been tried, but technical and economic considerations presage the limitation of the use of finely divided iron, and a short violent agitation. Finely divided lead would also serve, but is rather slow in action. The brine-lxiviant coming from the silver-copper precipitation is electrolyzed directly for its lead-content between iron electrodes. Insoluble anodes showed high current-costs and a deterioration of lixiviant in cyclic use. Because of the low metal concentration of the electrolyte, this being about 15 gm. of lead as a maximum, a very good circulation of electrolyte is required. Series-connections afford current-efficiencies of 60 to 70%, and parallel-connections 80 to 95%. Elec-

FIG. 4

trollysis is carried on to a lead concentration of about 1 gm. per litre, with but a natural slow decrease in the current-efficiency. If regeneration is to follow, the lead is entirely removed from the solution. The rate of decline of the current-efficiency, however, increased rapidly with solutions containing from 1 gm. of lead per litre down to those entirely free from lead. With air-agitation of the electrolyte, which makes it difficult to attain suitable efficiency and uniformity, it has appeared advisable to remove about half of the lead at current-densities of 50 to 60 amp. per sq. ft. of cathode-surface, and the remainder of the lead at 20 amp. per sq. ft. With a more uniform and efficient agitation of electrolyte, such as may be obtained by a rapid flow, or by rotating electrodes, the above condition does not hold, and one current-density may be taken for the entire period of 'stripping' the solution of lead. Thus the question of current-densities becomes the critical factor in the balance of yield versus plant and interest charges, plus the item of favor to the lower densities that cause less danger of carrying the

†Sims and Ralston, 'The Electrolytic Recovery of Lead from Brine Leaches,' *Met. & Chem. Eng.*, Oct. 1, 1916.

electrolysis too far. The curve in Fig. 4 shows the relation of the current-densities to the yield in the case of parallel connections and under ideal conditions of circulation of the electrolyte.

Proper circulation of the electrolyte and the use of appropriate current-densities causes a deposit of lead which is fine and semi-crystalline, the material being so soft that it can be pressed between the fingers somewhat like an amalgam. The deposit of lead adheres for the most part quite firmly to the cathodes, but not as a sheet. Failure to provide for a suitable circulation of the electrolyte causes the production of a light fluffy lead which fills up the spaces between the electrodes and floats about promiscuously. This lead is well-nigh worthless, as it cannot be pressed together, and hence cannot be gathered. It is practically an ooze. The sponge-lead is pressed free of solution and converted into briquettes under several tons pressure per square inch, and these briquettes are melted and cast into bullion. If sponge is allowed to air-dry without pressing it rapidly oxidizes, and the melting then must be done with the aid of a reducer.

The iron from the anodes that is dissolved by the electrolysis is the source of the ferrous chloride of which use is made in the regeneration of the lixiviant. As iron begins to settle out at 20 gm. per litre, regeneration must always be used before the iron builds up so far. In the event that iron settles out in the leaching of calcine, regeneration must follow each passage of the electrolytic step by the solution, before being again sent to the leach-vat.

In the process discussed a neutral brine has been used. Roasting transforms some of the lead sulphide into oxide and this is rendered soluble by slightly acidifying the brine-lixiviant. Such acidulation also has a markedly beneficial effect on the recovery of the silver. Acid need be added in small amount only, as, after roasting, but little acid-soluble, or acid-consuming, material can exist. Enough is added to take out the metal and then the leaching is carried to neutrality.

This article necessarily has been limited to a discussion of the general characteristics of a process developed in the laboratory on a small experimental scale. During the past few months about  $1\frac{1}{2}$  tons of ore per day has been treated and about 25 tons of lead-bullion has been recovered by it, assaying 999.5 fine. The cost of a commercial plant and the cost of its operation, as well as the question of suitable equipment, cannot be discussed at this time. The preliminary estimates, however, indicate that favorable economic results may be expected.

SILICON increases the tensile strength of pure iron from 38,000 to about 90,000 lb. per sq. in. in annealed samples, when 4% silicon is present. Beyond this the strength rapidly decreases. The elastic limit likewise steadily increases up to 4% silicon. The ultimate elongation and reduction of area are practically unaffected until 2.5% of silicon is reached. From this point the drop is rapid. Beyond 7% silicon forgeability ceases.

## Stadia-Reduction Chart

By EARL GLASS

The accompanying chart may be used for computing horizontal distances from stadia-readings and observed angles of inclination, the curves giving the correction to be subtracted. The horizontal distance of the observation will be found at the lower edge of the chart, and the degrees of inclination of the angles of elevation or depression appear at the left. Find the intersection of these two lines, and follow the curve from this point of intersection to the right-hand edge of the chart where the correction will be figure found on the margin. Thus, for a stadia-reading of 100 ft., and an angle of inclination of  $8^\circ$ , the correction is 2 ft., and the horizontal distance is

tance is the difference between the reading and the correction, or 98 ft. For a stadia-reading of 250 ft. and an angle of  $3^\circ 40'$ , the correction is 1 ft., and the horizontal distance is 249 feet.

PYRITE on being calcined has a tendency to explode, thus producing a large amount of extremely fine material that prevents free access of the air for further oxidation. This explains the irregularity in de-sulphurizing pyritic ores when burned in the McDougall type of roaster. Recent tests by C. R. Gyzander confirm the suggestion of Lunge, made many years ago, that the explosion is due to occluded carbonic acid gas. Fine crushing before calcination reduces this tendency, and the quantity of dust produced by grinding in the ball-mill is less than that resulting from explosion of the pyrite in the furnace.

ULTRA-VIOLET light is readily absorbed by colloids. A suspension of gel colloid acts as an effective screen for such rays.

## Velocity and Discharge in Ditches

By GEORGE HENRY ELLIS

The accompanying charts may be used for computing the velocity and discharge in small unlined earth ditches. The quantities have been calculated by using Kutter's formula,  $n$  being taken as 0.0225, which is an average

second. By interpolation, the depth is found to be approximately 1.85 ft. The velocity for this discharge is found by interpolation to be 2.3 ft. per second. The diagram may be used also to solve such problems as, given a canal 6 ft. wide in which it is desired that the velocity be 2 ft. per second, what is the greatest depth that can be permitted without delivering more than 40

CHARTS FOR COMPUTING DISCHARGE OF EARTH DITCHES.

value for earth canals in fair condition. Thus for a canal 6 ft. wide flowing 2 ft. deep, having a slope of 0.0004 or practically 2 ft. to the mile, the velocity is found to be approximately  $1\frac{1}{2}$  ft. per second and the discharge 30 cu. ft. per second. For a canal 8 ft. wide, flowing 3 ft. deep, with a slope of 0.0002 or 1 ft. to the mile, the velocity is slightly under  $1\frac{1}{2}$  ft. per second and the discharge is 60 cu. ft. per second. Again, given a canal 8 ft. wide, with a slope of 0.0009 or  $4\frac{1}{2}$  ft. per mile; required the depth of water to give a discharge of 50 cu. ft. per

cu. ft. per second, and what would be the corresponding slope? The depth is found to be 2 ft. and the slope approximately 0.00066 or 3.3 ft. per mile. Again, given a canal 8 ft. wide flowing 2.5 ft. deep; required the slope necessary for a discharge of 50 cu. ft. per second, and also the corresponding velocity. The slope is found to be slightly under 0.0003 or  $1\frac{1}{2}$  ft. per mile and the corresponding velocity, computed by interpolation, is 1.6 ft. per sec. To deliver 60 cu. ft. per sec. it would require a slope of 0.0004 and a velocity of 1.9 ft. per second.

# Detrital Copper Deposits

By W. TOVOTE

Detrital copper deposits, similar in derivation to gold placers are not infrequent in the South-West. From personal observation I know them to exist in the following localities in Arizona:

Castle Dome, near Miami, Gila county.

Ray, Pinal county.

Copper Butte, near Ray.

Copper Basin, near Prescott, Yavapai county.

Copper Creek, near Hillside, Yavapai county.

Mineral Park, near Chloride, Mojave county.

In spite of this wide distribution the general features are the same. They are

1. The source of the copper is not veins, but disseminated pyritic deposits in porphyry or schist.

2. The distribution of the copper is not uniform, but follows certain channels, suggesting mechanical concentration.

3. The copper-conglomerate is accompanied by similar conglomerate showing rusty iron-oxide cement, barren of copper. This iron conglomerate usually covers a far greater area.

4. The copper content is largely in the cement, being concentrated along later fissures and fracture-zones, suggesting chemical concentration and causing the ore to appear sometimes as deposited in a 'gash-vein,' because the ore invariably ceases at a shallow depth.

5. The predominant minerals are chrysocolla and the mixtures of chrysocolla with the oxides of iron and manganese, commonly called copper pitch; azurite and impure cuprite are rare and malachite is exceptional. Both the oxides of iron and manganese occur independently without admixture of copper, but while iron is prominent in the barren breccia, manganese seems to follow closely the copper. Much of the earthy manganese (wad) assays well in copper, without showing the color of copper. This is one reason why those unfamiliar with these deposits under-estimate the grade of the ore.

All the deposits mentioned, with exception of the Copper Creek area, have produced shipping ore, but only the Copper Butte and possibly the Mineral Park are of economic importance. A short sketch of the individual occurrences follows:

**CASTLE DOME.** Cemented gravel in creek-beds, issuing from the pyritized granite-massive of Porphyry Mtn. Apparently originally arranged in several terraces (lake-beds), but much dissected by recent erosion. Sorted ore as high as 15 to 20% copper has been obtained in small quantities. The deposit is not extensive.

**RAY.** Small areas of high-grade conglomerate in the canyons crossing the Ray orebody. The conglomerate is angular and deposited in immediate vicinity of its source.

**COPPER BUTTE.** This is the most notable member of the group. At least 30,000 tons of ore averaging about 4% copper is indicated in one mass right at the surface. Several gash-veins with narrow high-grade streaks are found in the immediate vicinity. The ore is in the pre-dacite conglomerate, named the Whitetail Conglomerate by F. L. Ransome in his *Globe and Ray* reports. It was described a few years ago in the *MINING AND SCIENTIFIC PRESS* by F. H. Probert as a 'volcanic neck' and is given as such in Weed's 'Mines Handbook.' How this misconception arose is not clear. This conglomerate extends as a broad belt from the Gila river to Copper Butte, pointing to Ray as its source. The copper-bearing area is surrounded by a broad belt of bright red conglomerate, which will average about 0.5% copper indicating a slight admixture of cuprite. Practically all the pebbles are slightly water-worn fragments of schist with occasional pieces of limestone, quartzite, and diabase. Below the schist-conglomerate lies another conglomerate composed largely of quartzite and again deeper another of limestone fragments, repeating in inverse order the sequence of the Paleozoic sediments exactly as they would be attacked by the agencies of erosion. The conglomerate is overlain by remnants of the dacite flow, and dissected by post-dacite faulting and erosion. Every trace of both dacite and conglomerate has been removed from the area intervening between Copper Butte and Ray, where the erosion has cut down to the diabasic and granitic rocks. The conglomerate belt is apparently a broad river-channel or a lake-bed. Copper-bearing areas recur in it at several places, but none of them is as extended or important as the Copper Butte ground. The ore is principally in the cement, but a few pebbles with copper stain are found also. The Whitetail conglomerate here, as everywhere else, is of variable thickness. It indicates the first lacustral and fluvial deposition accompanying the subsidence of a sharply dissected land-area during a period of great geologic unrest with frequent shifting of stream-channels and drainage-systems. It is odd to consider that only such a shifting of erosion has saved the Ray orebodies from complete destruction.

The best exposure of the entire deposit, here over 200 ft. thick from limestone-conglomerate at the bottom resting on diabase to schist-conglomerate on the top, and conformably overlain by the dacitic flow, is found on the west slope of Copper Butte peak. The bottom of the dacite flow is marked by the bed of obsidian described by Ransome. The occurrence at Copper Butte has so many features in common with the copper deposits of the Black Warrior and Black Copper mines near Inspiration, that I am convinced that they are similar in origin. Near the Black Warrior the Whitetail con-

glomerate is lacking, but copper ore is found in the lowest part of the dacite, where chrysocolla, frequently in concentric aggregates, replaces the dacite. The dacite preserves its glassy texture, but is decomposed and crumbling as a rule. While the deposition of the copper is strictly by chemical replacement, chemical action has played an important part in the Copper Butte deposit also. The copper is concentrated most along post-dacite faults of N 30° W strike, traversing the conglomerate. Veins of this strike, with 20% ore, persist below the horizon that generally marks the bottom of the copper-bearing strata in the conglomerate.

**COPPER BASIN.** Creek-gravel, well cemented and indicating former terraces, now dissected. Derived from the pyritized monzonite, which is the principal country-rock. The conglomerate contains large boulders, usually barren, and cement rich in manganese with iron oxide and copper salts. Azurite is common. The copper has not traveled far and marks practically the lode-croppings. This is probably due to the fact that the groundwater comes to within a few feet of the surface. Good ore has been shipped from here. The conglomerate led to the discovery of the veins and lodes now being worked.

**COPPER CREEK.** Creek-gravels, mostly with iron cement but containing irregular areas of copper-bearing gravel; all well cemented. Material derived from the pyritized monzonite, in which the Bagdad Copper Co. has proved about 15 to 20 million tons of disseminated ore.

**MINERAL PARK.** Gravel-beds skirting the base of the masses of pyritized porphyry in Niggerhead and Congress mountains. The surface is much obscured by later barren gravel. The granitic boulders are barren; copper occurs in the cement, apparently in well defined channels. Ore of about 3% copper has been proved to a depth of 25 feet.

In conclusion I would say that none of these copper-conglomerates can be considered a true placer, because in every case the chemical concentration and re-deposition of copper from solution in surface-waters is far more important than the mechanical action of transportation by water. The Copper Butte is nearest to being a true placer; there the apparent source of the ore is over six miles away; the other extreme is Copper Basin, where there is practically no mechanical transportation at all. Copper Butte, for the same reason, is also the only one where copper is found to any extent in the pebbles. Otherwise the genesis is probably simply that copper was leached from the pyritic copper deposits as a sulphate and found a ready precipitant in the cement of near-by gravel deposits. In some cases, where erosion was rapid or oxidation shallow, boulders of ore found their way into the conglomerate together with barren material, so that they give the impression of true placer material, but ore of economic grade will probably never be found in deposits of this type unless due to chemical deposition and concentration. The copper can be derived as well from the gravel itself as from the original source of the gravel.

## Montana Mineral Production

A mid-year report by the U. S. Geological Survey on the mines of Montana shows a large output of silver, copper, and zinc, in spite of delays by severe winter weather and by fire in the mines at Butte. As the six-month period closes a labor strike threatens to interfere with the year's record. The copper production of the first four months in 1917 was decidedly higher than during the corresponding period of 1916. The total output for 1916 was estimated at 357,000,000 lb. Next in importance is the silver output, which increases or decreases with the production of copper. In 1916 the production of silver was about 16,000,000 oz. The Anaconda Copper Co.'s smelting plants were averaging 28,200,000 lb. of copper monthly during the first four months of 1917, and the East Butte smelter 1,786,000 lb. Each of these establishments had higher averages in certain months, and may increase their output materially before the end of 1917. The estimated quantity of recoverable zinc produced in the State during 1916 was about 227,000,000 lb. With the increase in the number of shippers to the electrolytic plant this may be exceeded in 1917. At the Butte & Superior the output of the first quarter was not up to the average of 1916, owing to shaft-sinking and changes in the flotation equipment. The monthly average was 13,360,000 lb. of zinc in concentrate, against about 15,000,000 lb. in 1916. For several years the largest zinc producers were the Butte & Superior and the Elm Orlu mines. In addition to these, the Emma, Lexington, and Davis Daly are now large shippers to the Anaconda zinc concentrator. The concentrate is calcined at Anaconda and shipped to Great Falls for treatment at the electrolytic zinc works. The Ophir mill at Butte, operated by the Butte Detroit Copper & Zinc Co., has been converted into a zinc concentrator for custom ore. In Fergus county and at Marysville, in Lewis and Clark county, the output of gold has been increased. The new cyanide mill at Bannock, in Beaverhead county, was recently started, and the first lot of bullion was shipped. At Giltedge another cyanide mill is under construction for the treatment of gold ores, and near Helena one gold mill and a concentrator have been put in commission.

ACID-RESISTING alloys, almost completely insoluble in nitric and other acids, have been made in the Engineering Experiment Station of the University of Illinois by mixing chromium, copper, and nickel with small quantities of tungsten or molybdenum. The results were given in Bulletin 93 of the Experiment Station.
